Autocalibration github

<https://github.com/freakonometrics/autocalibration/>

The following graph is a visualisation of $s \mapsto \mathbb{E}[Y|\pi(\mathbf{X}) = s]$ where s is some premium level, for the three models π . If π is close to μ the curve should be close to the first diagonal.

Observe that $\mathbb{E}[Y|\pi(\mathbf{X}) = F_\pi^{-1}(u)] \geq F_\pi^{-1}(u)$ which reflects the local bias of the estimator π (except perhaps for very low risks). Other plots can be used to visualised using the following plots.

Since $\mathbb{E}[Y|\pi(\mathbf{X}) = F_\pi^{-1}(u)] \sim F_\pi^{-1}(u)$ if $\pi \approx \mu$, we can plot $\mathbb{E}[Y|\pi(\mathbf{X}) = F_\pi^{-1}(u)]/F_\pi^{-1}(u)$ which should be close to 1,

Warning and Preamble (1)

Important to define what probabilities are (see  in French,  in English, from the *Casualty Actuarial and Statistical Task Force (CASTF) Reading Club*)

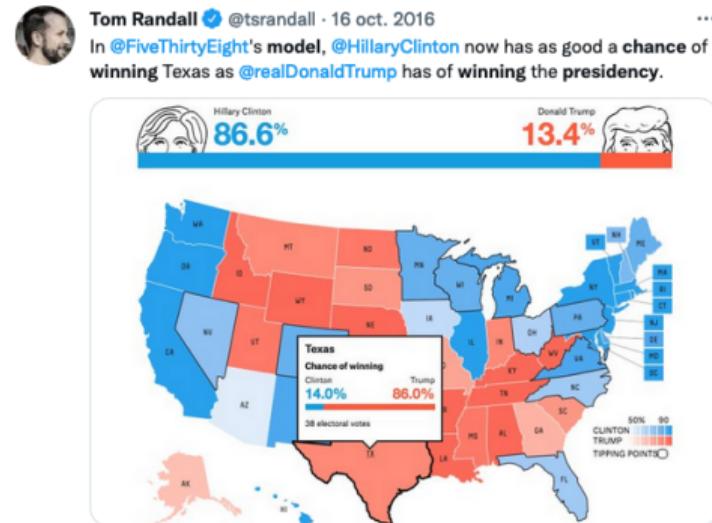

“Probability is the most important concept in modern science, especially as nobody has the slightest notion what it means”, Russell (1929), quoted in Bell (1945)

Very often, the “physical” probabilities receive an objective value only posterior on the basis of the law of large numbers, the empirical frequency converge towards the probability (frequentist theory of probabilities)

$$\underbrace{\frac{1}{n} \sum_{i=1}^n \mathbf{1}(X_i \in A)}_{\text{(empirical) frequency}} \xrightarrow{\text{a.s.}} \underbrace{\mathbb{P}(X \in A)}_{\text{probability}} \text{ as } n \rightarrow \infty$$

Warning and Preamble: Probability to win an election ?

How to interpret this "probability of winning" ?

How to interpret a "confidence interval" on that probability ? (@AdamSinger)

Warning and Preamble (1)

This frequentist approach is unable to make sense of the probability of a "single singular event", as noted by von Mises (1928, 1939).

"When we speak of the 'probability of death', the exact meaning of this expression can be defined in the following way only. We must not think of an individual, but of a certain class as a whole, e.g., 'all insured men forty-one years old living in a given country and not engaged in certain dangerous occupations'. A probability of death is attached to the class of men or to another class that can be defined in a similar way. We can say nothing about the probability of death of an individual even if we know his condition of life and health in detail. The phrase 'probability of death', when it refers to a single person, has no meaning for us at all."

Warning and Preamble (2)

Econometrics is based on a probabilistic model, unlike most machine learning approaches, see [Charpentier et al. \(2018\)](#)

- ▶ in SVMs, the distance to the separation line is used as a score which can then be interpreted as a probability - [Platt scaling](#), [Platt et al. \(1999\)](#) or [isotonic regression](#) [Zadrozny and Elkan \(2001, 2002\)](#) (see also [Niculescu-Mizil and Caruana \(2005\)](#) “good probabilities”)
- ▶ in Neural Nets, [Rumelhart et al. \(1985\)](#), [Rumelhart et al. \(1986\)](#) [Hertz et al. \(1991\)](#) and [Buntine and Weigend \(1991\)](#) proposed to formalize back-propagation in a [Bayesian context](#), taken up by [MacKay \(1992\)](#) and [Neal \(1992\)](#). State of the art in [Neal \(2012\)](#), more than 25 years ago (or more recently [Neal \(2012\)](#) [Theodoridis \(2015\)](#), [Gal and Ghahramani \(2016\)](#) and [Goulet et al. \(2021\)](#))

Motivation and Context

Ph.Demetri @PhDemetri · 6 avr. 2021

All this talk about XGboost prompted me to try it again on some toy datasets I have laying around.

...

The long and the short of it is: XGBoost results in a better AUC than my logistic regression (99.7 v 87) but XGB is so poorly calibrated it doesn't make sense to trust the probs

Calibration

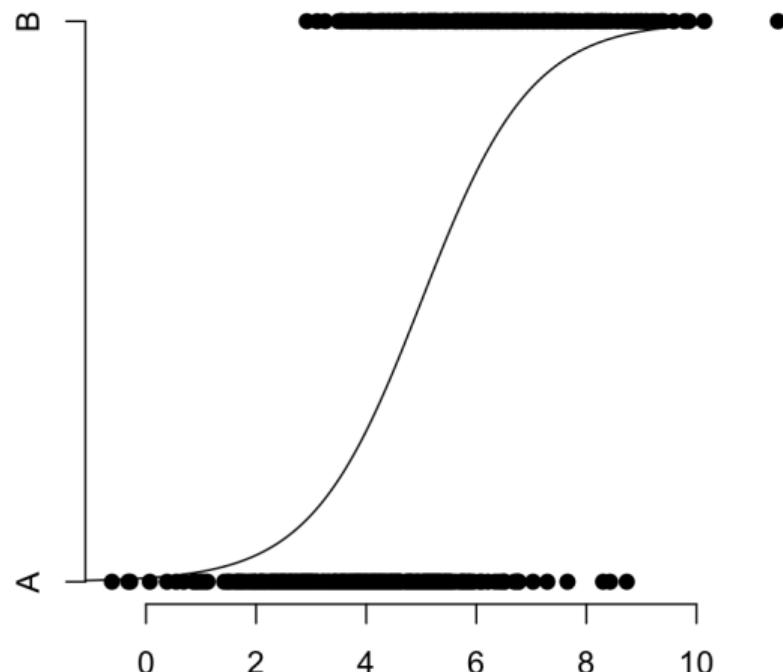

Dataset (x_i, y_i) , $y_i \in \{A, B\}$,

$$\mathbb{P}[Y = 'A'] = \frac{\exp(\beta_0 + \beta_1 x)}{1 + \exp(\beta_0 + \beta_1 x)}$$

Convert into $y_i \in \{0, 1\}$,

$$m(x) = \frac{\exp(\beta_0 + \beta_1 x)}{1 + \exp(\beta_0 + \beta_1 x)}$$

(classical logistic regression)

Calibration

Given $p \in (0, 1)$, let $\mathcal{X}_p \subset \mathbb{R}$ such that $\forall x \in \mathcal{X}_p, m(x) = p$

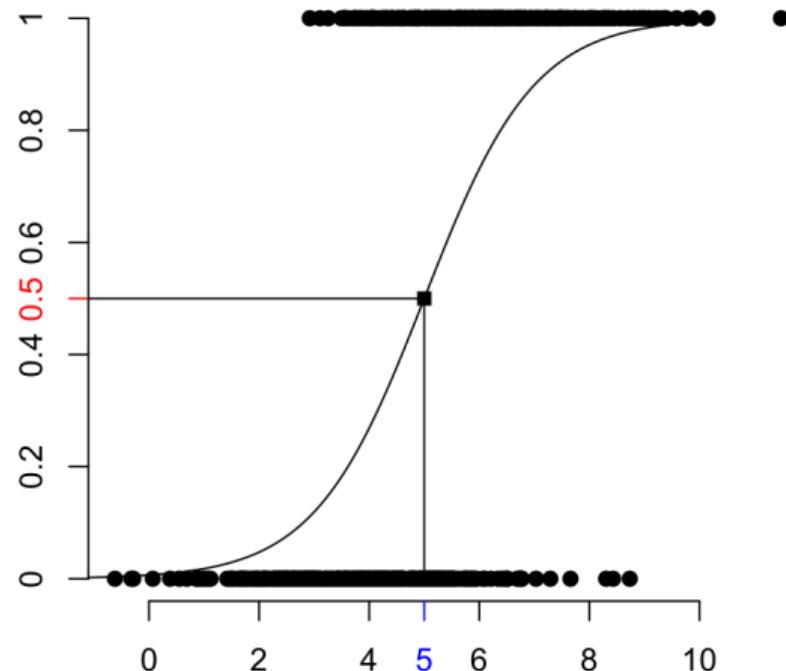

We want to compute

$$\mathbb{E}[Y|m(X) = p]$$

or a sample version

$$\frac{1}{\#\mathcal{V}_p} \sum_{i:x_i \in \mathcal{V}_p} y_i$$

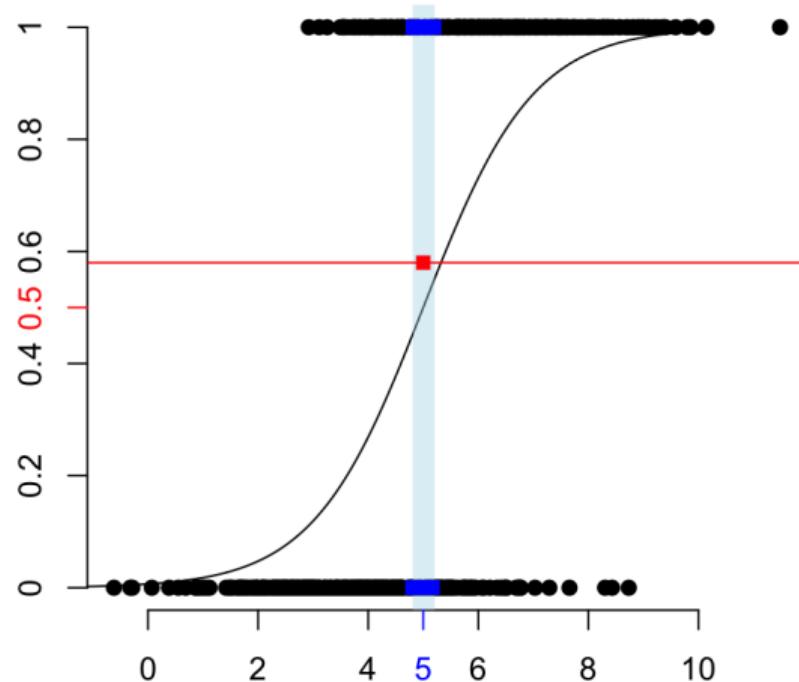

where \mathcal{V}_p is a neighborhood of x

Calibration

Given \mathcal{V}_p is a neighborhood of x

$$\frac{1}{\#\mathcal{V}_p} \sum_{i:x_i \in \mathcal{V}_p} y_i$$

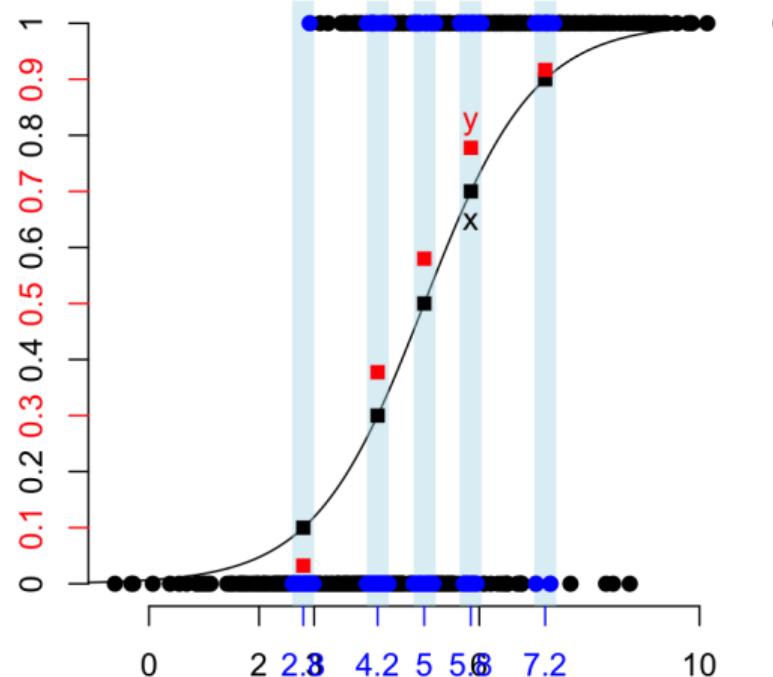

Calibration

for various $p \in (0, 1)$, we can approximate

$$\mathbb{E}[Y|m(X) = p]$$

using averages on neighborhoods of $\mathcal{X}_p \subset \mathbb{R}$

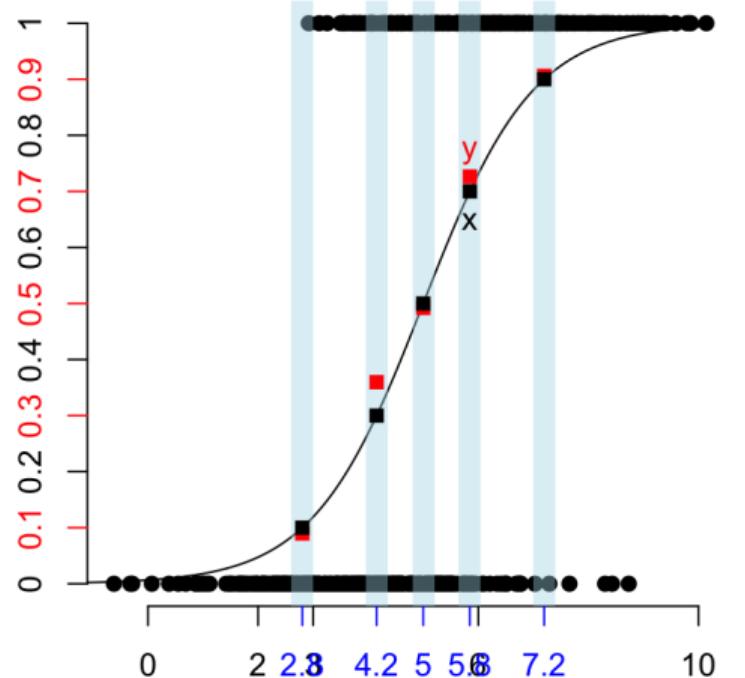

Calibration

We can also estimate

$$\mathbb{E}[Y|m(X) = p]$$

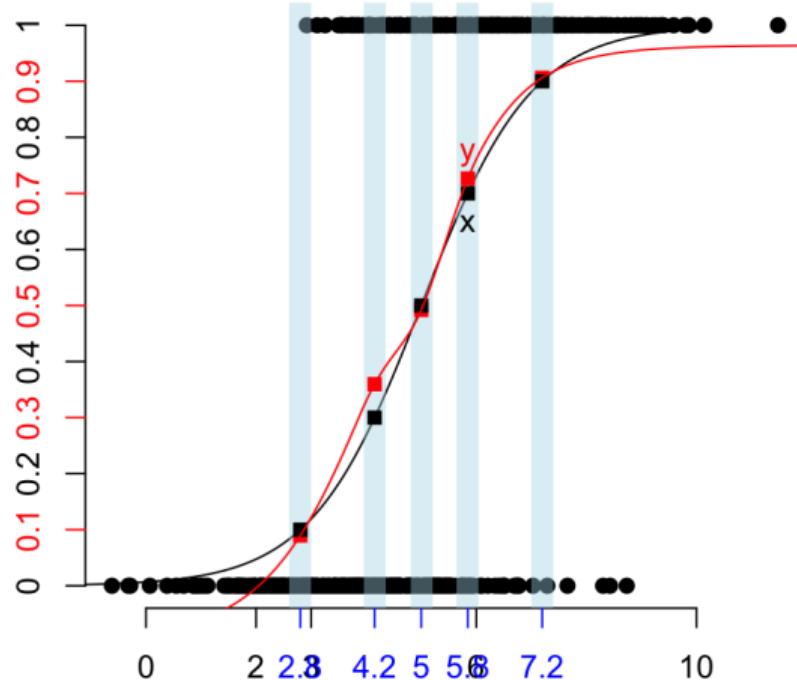

using a local regression of Y against $m(X)$,
on $\{m(x_i), y_i\}$

Calibration

Consider function

$$p \mapsto \mathbb{E}[Y|m(X) = p]$$

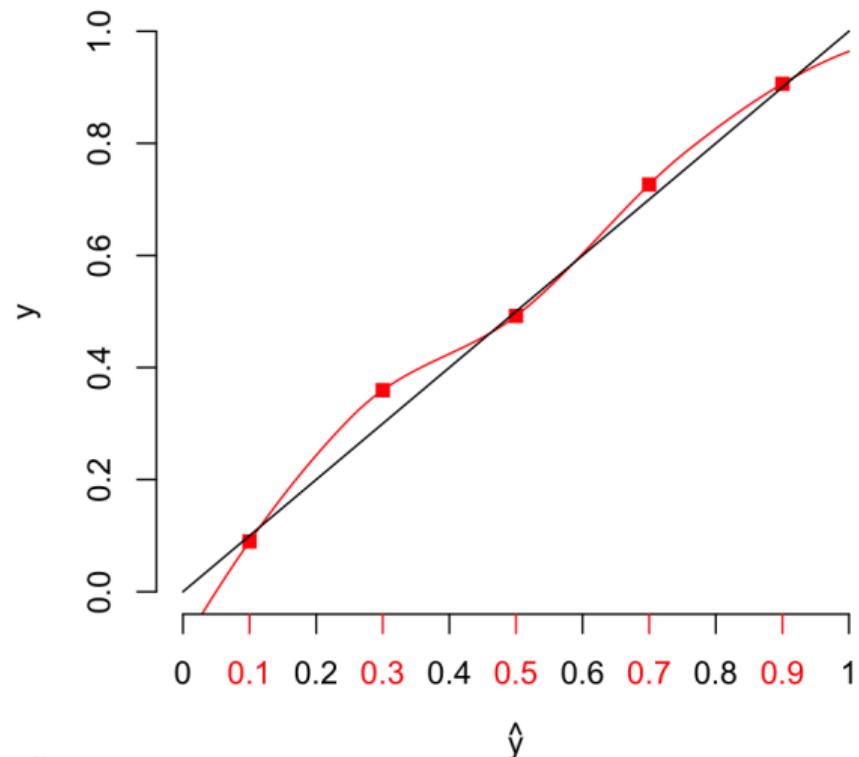

Calibration

If the model is well-calibrated

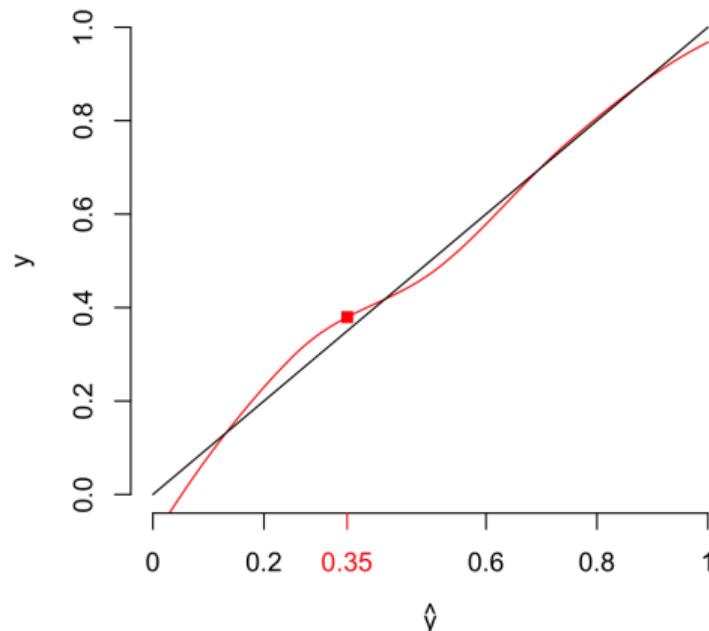

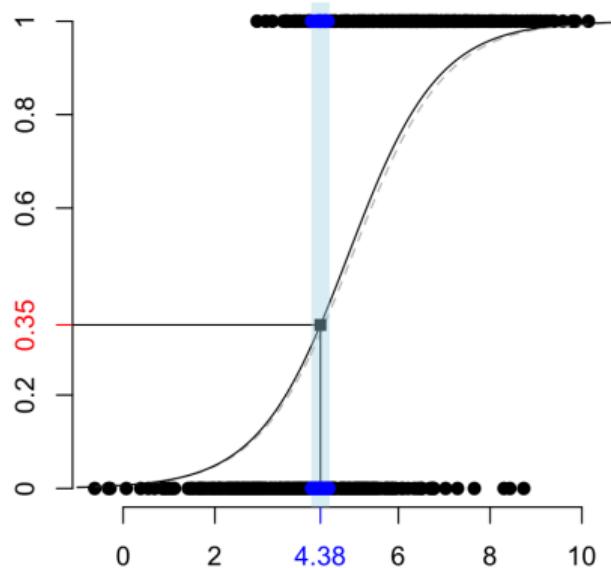

$$\mathbb{E}[Y|m(X) = p] \sim p$$

if not, m is "locally biased"

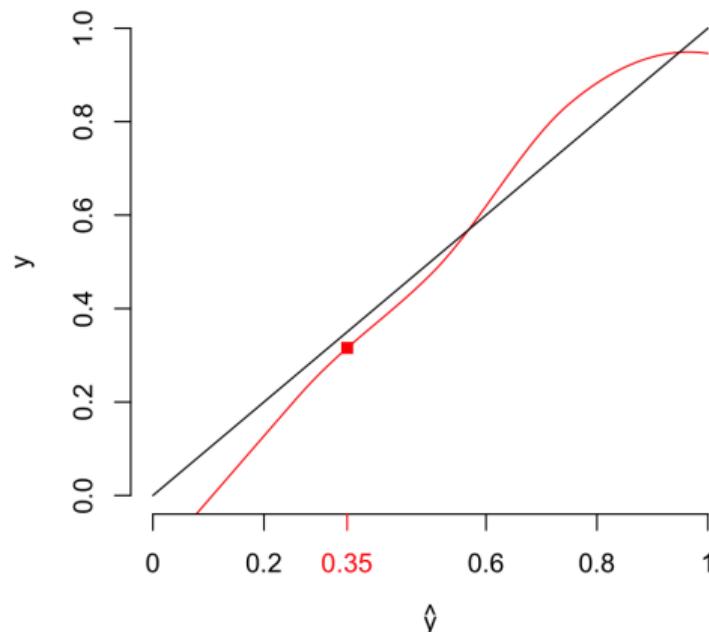

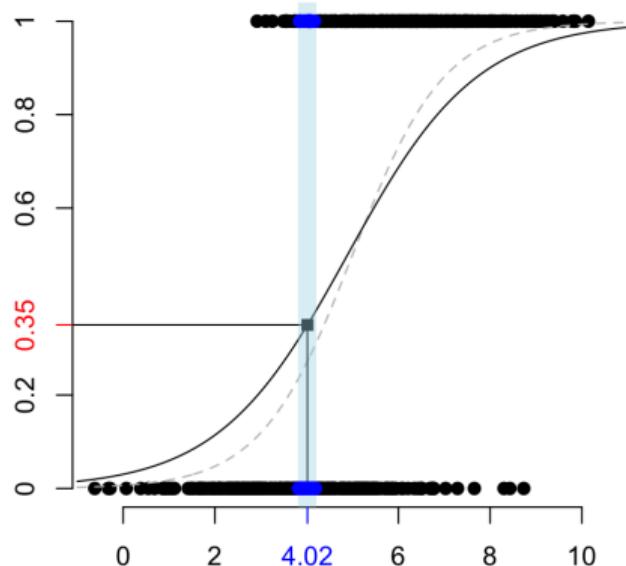

Calibration

Let $\hat{m}(x) = \frac{\exp(\hat{\beta}_0 + \hat{\beta}_1 x)}{1 + \exp(\hat{\beta}_0 + \hat{\beta}_1 x)}$ denote the prediction of a logistic regression

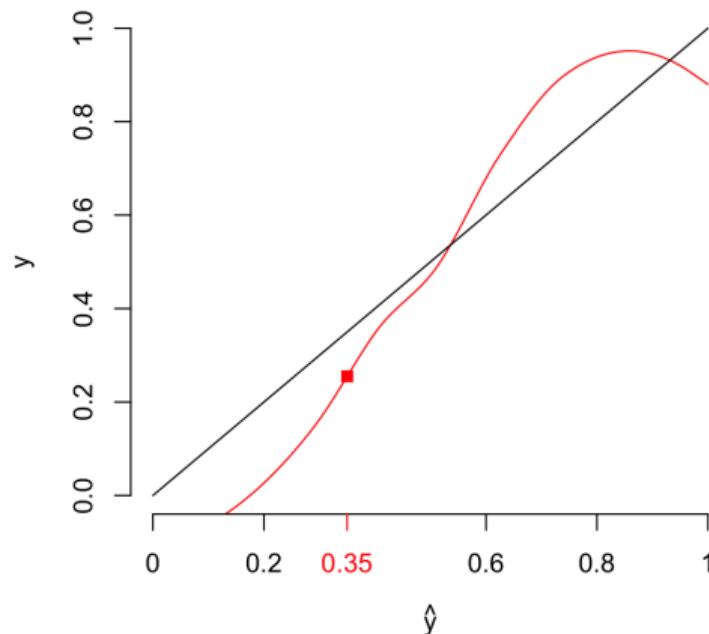

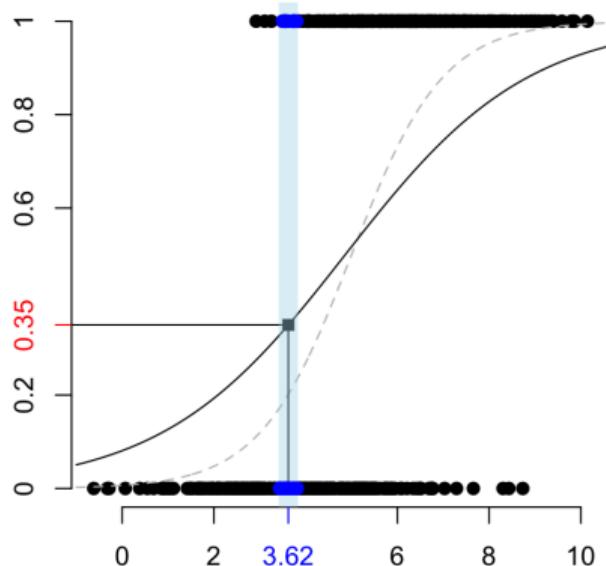

Calibration

Consider a penalized Ridge logistic regression $\hat{m}(x) = \frac{\exp(\hat{\beta}_0 + \hat{\beta}_1 x)}{1 + \exp(\hat{\beta}_0 + \hat{\beta}_1 x)}$

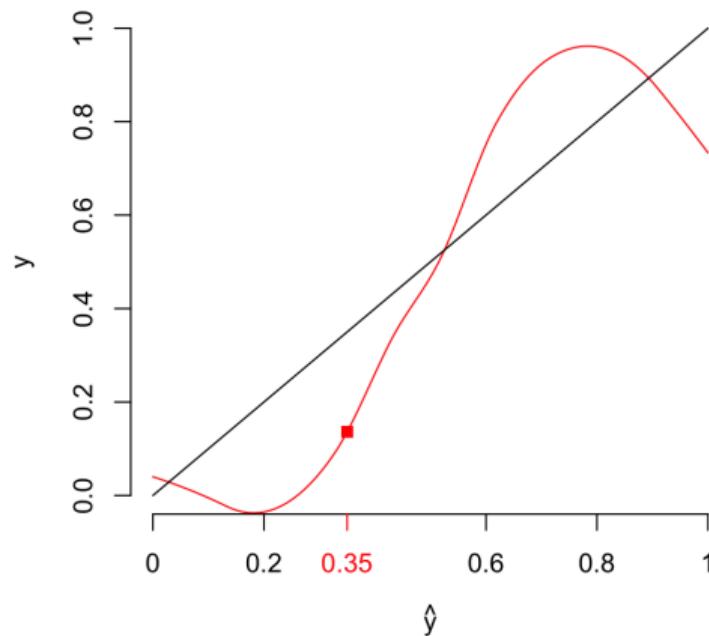

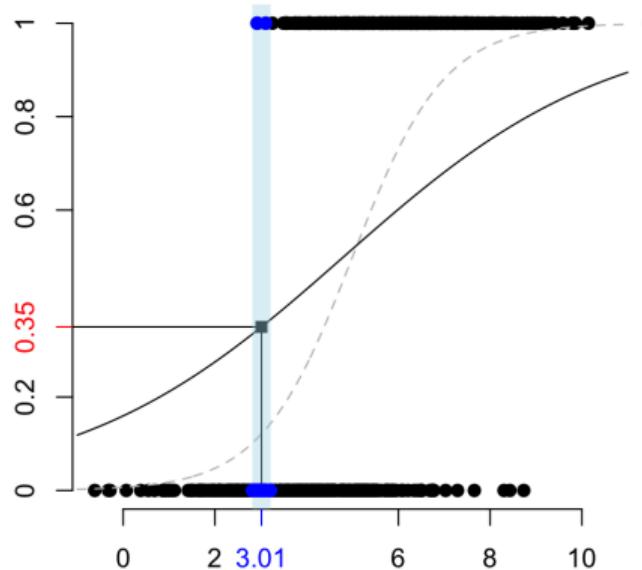

Calibration

Consider a penalized Ridge logistic regression $\hat{m}(x) = \frac{\exp(\hat{\beta}_0 + \hat{\beta}_1 x)}{1 + \exp(\hat{\beta}_0 + \hat{\beta}_1 x)}$

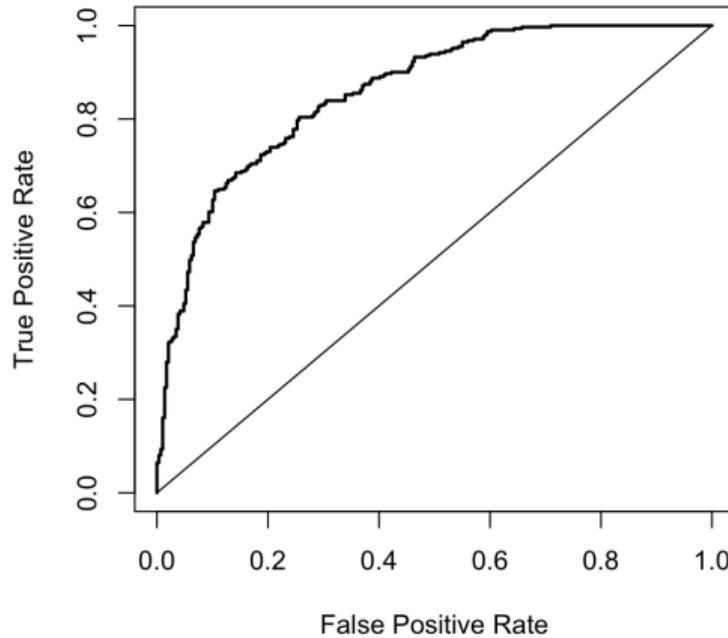

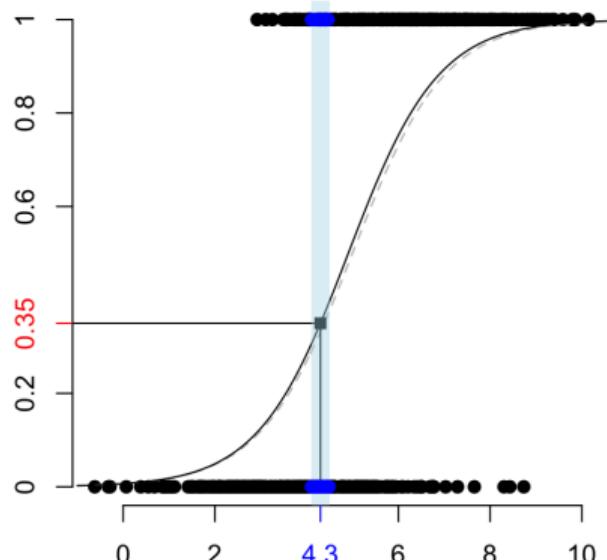

Calibration

Consider a penalized Ridge logistic regression $\hat{m}(x) = \frac{\exp(\hat{\beta}_0 + \hat{\beta}_1 x)}{1 + \exp(\hat{\beta}_0 + \hat{\beta}_1 x)}$

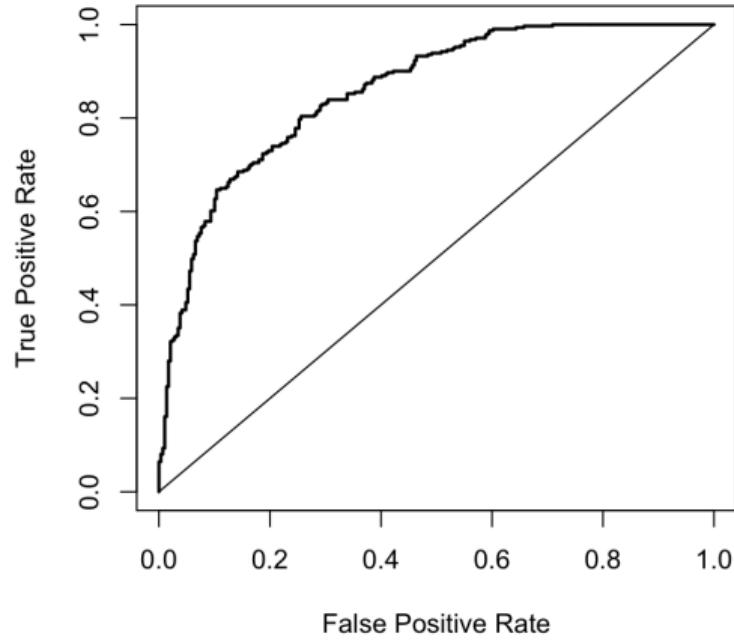

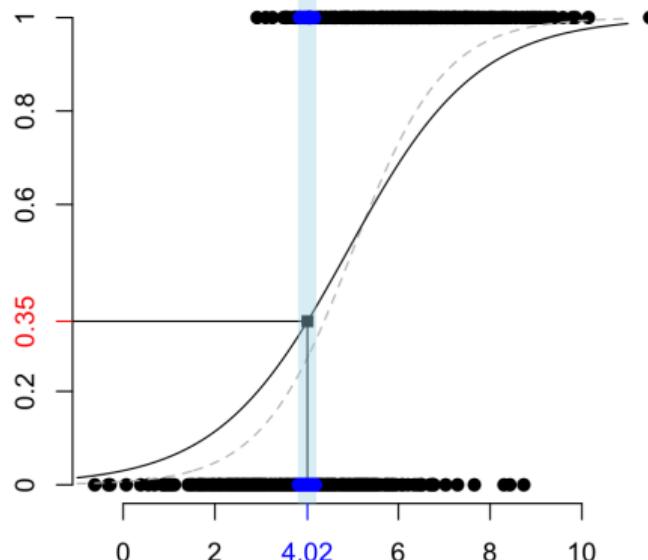

Calibration vs. Accuracy

We can get ROC curves for those Ridge logistic regressions

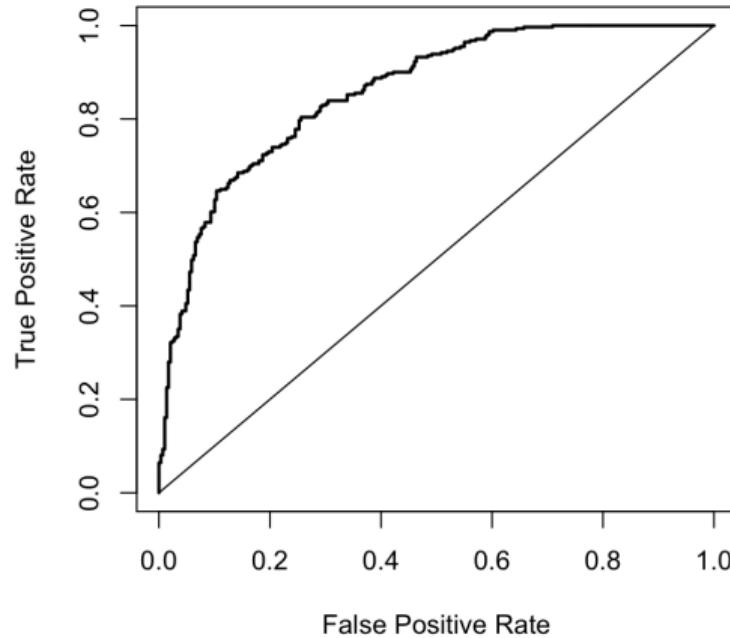

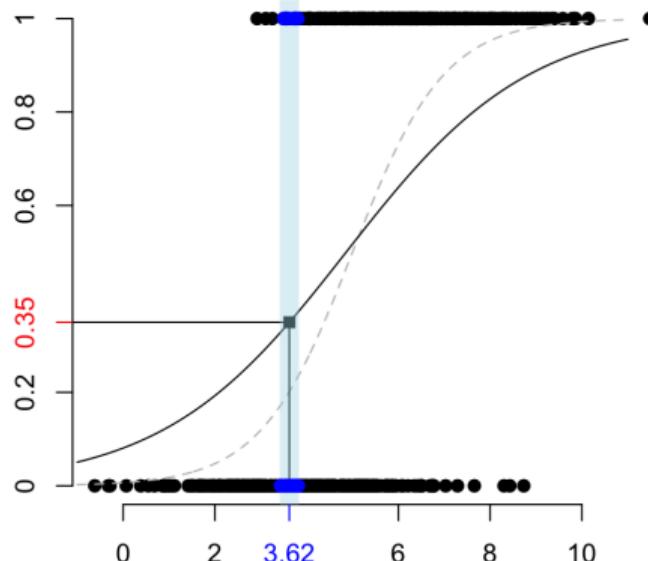

Calibration vs. Accuracy

We can get ROC curves for those Ridge logistic regressions

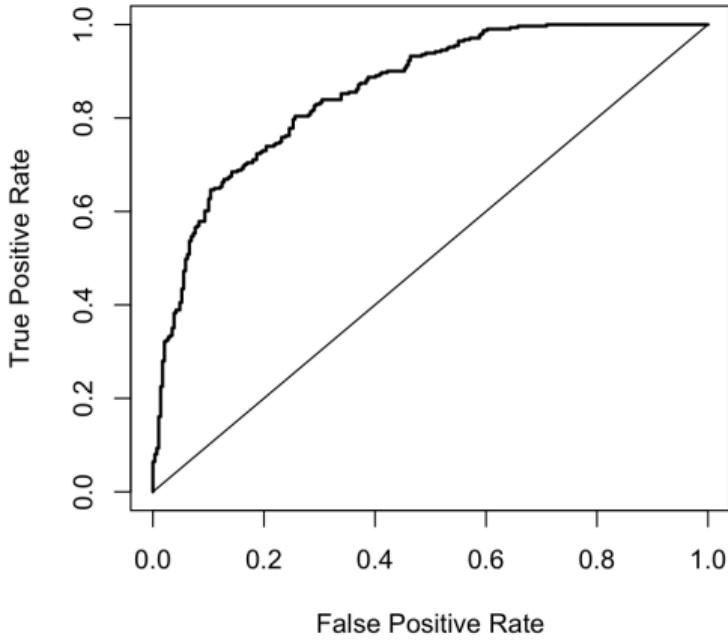

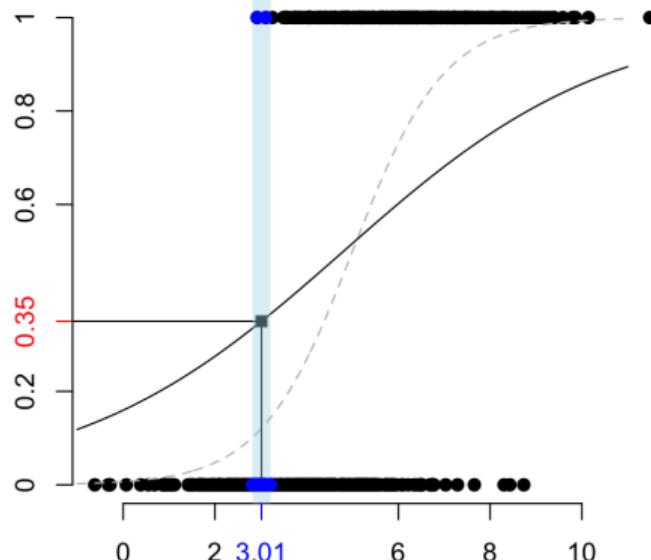

Calibration vs. Accuracy

We can get ROC curves for those Ridge logistic regressions

Calibration vs. Accuracy

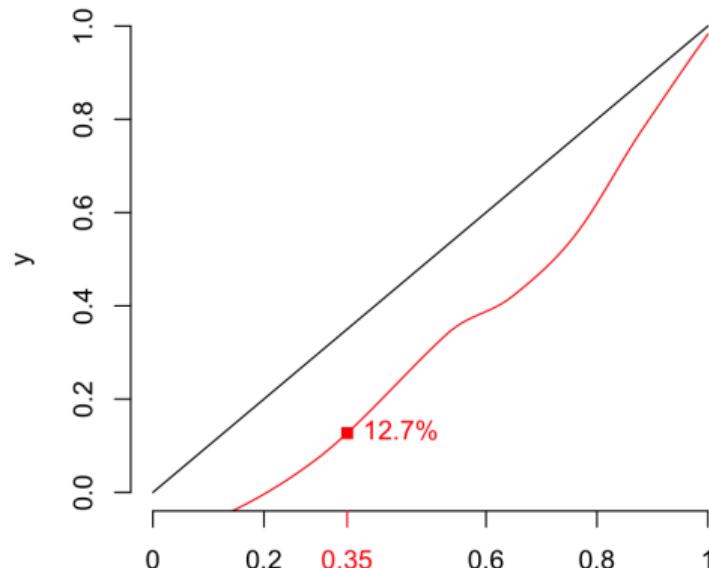

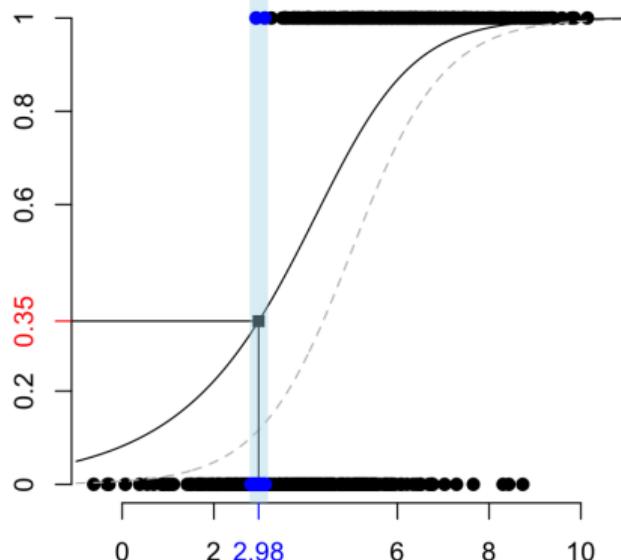

We can get ROC curves for those Ridge logistic regressions

Calibration

Consider the square root of the logistic regression $\hat{m}(x) =$

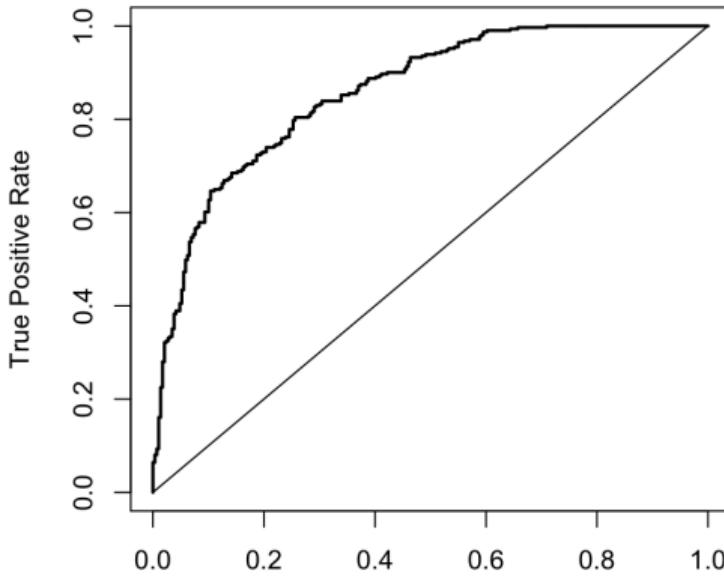

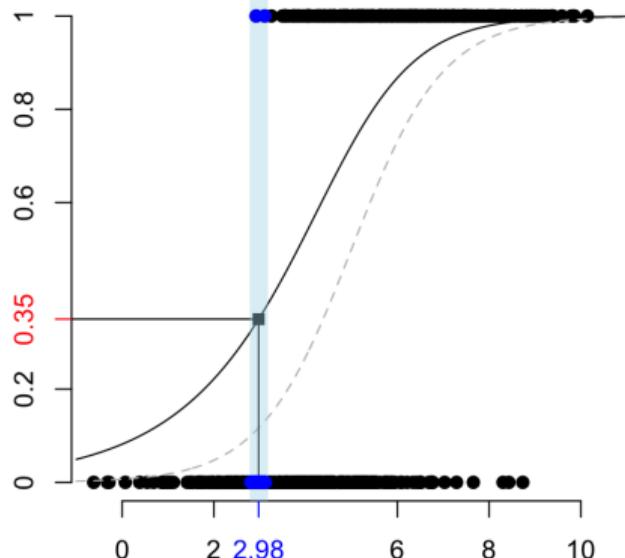

$$\sqrt{\frac{\exp(\hat{\beta}_0 + \hat{\beta}_1 x)}{1 + \exp(\hat{\beta}_0 + \hat{\beta}_1 x)}}$$

Calibration and Accuracy

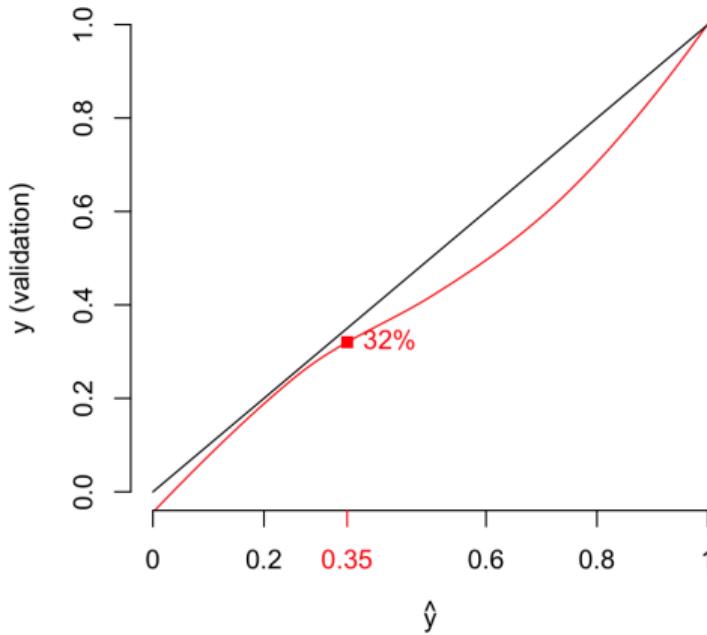

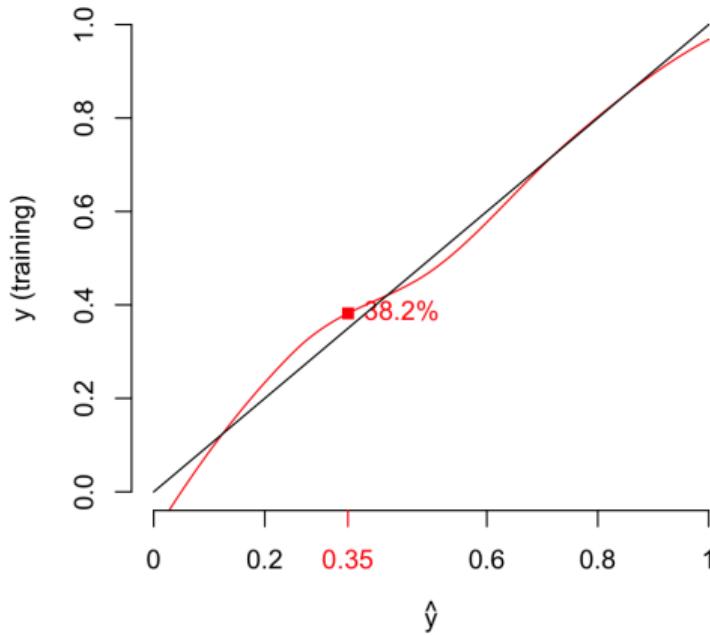

Consider the square root of the logistic regression $\hat{m}(x) =$

$$\sqrt{\frac{\exp(\hat{\beta}_0 + \hat{\beta}_1 x)}{1 + \exp(\hat{\beta}_0 + \hat{\beta}_1 x)}}$$

Distribution of scores, ← logistic regression vs. random forest → (training dataset)

“deep neural networks tend to be over-confident and poorly calibrated after training”, Wang et al. (2021)

“Guo et al. (2017) have shown that modern neural networks are poorly calibrated and over-confident despite having better performance”, Müller et al. (2019)

Accuracy, Calibration & Bias

For classification problems, **calibration** measures how well your model's scores can be interpreted as probabilities. **Accuracy** measures how often your model produces correct answers.

“Accuracy is a qualitative term referring to whether there is agreement between a measurement made on an object and its true (target or reference) value. Bias is a quantitative term describing the difference between the average of measurements made on the same object and its true value..” Handbook of Statistical Methods

“Well calibrated classifiers are probabilistic classifiers for which the output can be directly interpreted as a confidence level. For instance, a well calibrated (binary) classifier should classify the samples such that among the samples to which it gave a[predicted probability] value close to 0.8, approximately 80% actually belong to the positive class.” scikit learn: Probability calibration

Calibration

*“Suppose that a forecaster sequentially assigns probabilities to events. He is **well calibrated** if, for example, of those events to which he assigns a probability 30 percent, the long-run proportion that actually occurs turns out to be 30 percent. ”, Dawid (1982), The Well-Calibrated Bayesian,*

*“Out of all the times you said there was a 40 percent chance of rain, how often did rain actually occur? If, over the long run, it really did rain about 40 percent of the time, that means your forecasts were **well calibrated** ”, Silver (2012), The signal and the noise,*

“we desire that the estimated class probabilities are reflective of the true underlying probability of the sample ”, Kuhn and Johnson (2013) Applied Predictive Modeling

See Murphy and Epstein (1967), Roberts (1968), Gneiting and Raftery (2005) on ensemble methods for weather forecasting, or more generally Lichtenstein et al. (1977), Oakes (1985), Gneiting et al. (2007).

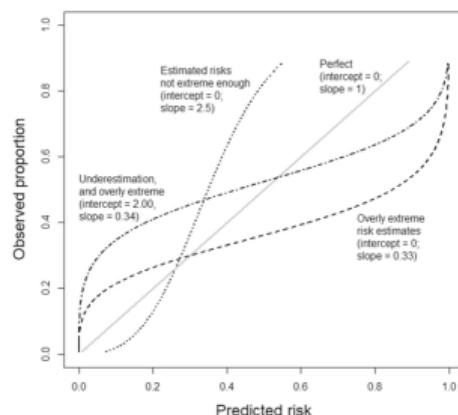

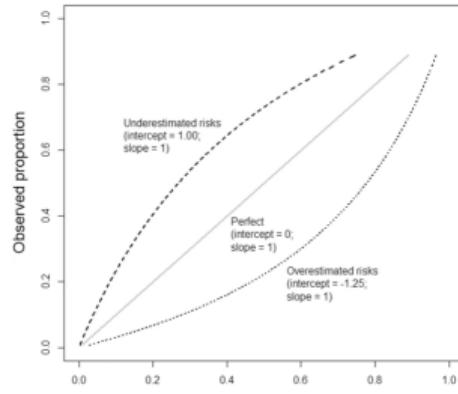

Calibration & Auto-calibration

As explained in Van Calster et al. (2019), "among patients with an estimated risk of 20%, we expect 20 in 100 to have or to develop the event",

- ▶ If 40 out of 100 in this group are found to have the disease, the risk is **underestimated**
- ▶ If we observe that in this group, 10 out of 100 have the disease, we have **overestimated** the risk.

Hosmer-Lemeshow test, from Hosmer Jr et al. (2013) (logistic regression), and Brier score, from Brier et al. (1950) and Murphy (1973)

Function plotted in psychological papers Keren (1991)

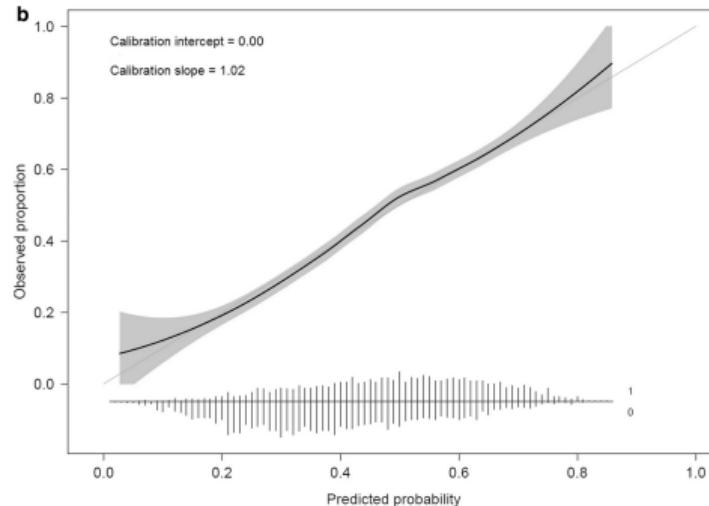

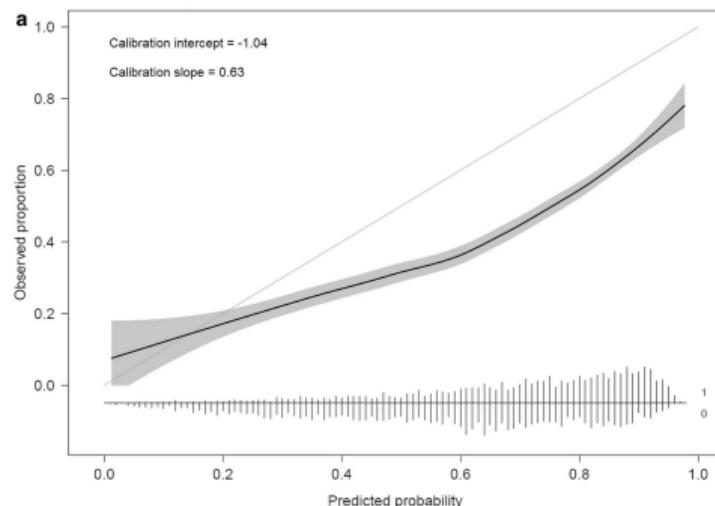

Calibration & Auto-calibration

Krüger and Ziegel (2021) Generic conditions for forecast dominance,

Definition 3.1 “*the forecast X of Y is an auto-calibrated forecast of Y if $\mathbb{E}(Y|X) = X$ almost surely*”, or $\mathbb{E}(Y|\hat{Y} = y) = y, \forall y$

Van Calster et al. (2019) Calibration: the Achilles heel of predictive analytics

Calibration & Fairness

Consider a binary outcome Y , a binary protected attribute P , and a prediction \hat{Y} .

Classical fairness concepts are related to **independence** ($\hat{Y} \perp\!\!\!\perp P$) or **separation** ($\hat{Y} \perp\!\!\!\perp P | Y$)

Based on **sufficiency** ($Y \perp\!\!\!\perp P | \hat{Y}$), [Sokolova et al. \(2006\)](#) introduced a concept related to calibration (and later taken up by [Kleinberg et al. \(2016\)](#) and [Zafar et al. \(2017\)](#)).

We have **calibration parity** if

$$\mathbb{P}[Y = 1 | \hat{Y} = y, P = 0] = \mathbb{P}[Y = 1 | \hat{Y} = y, P = 1], \quad \forall y \in (0, 1).$$

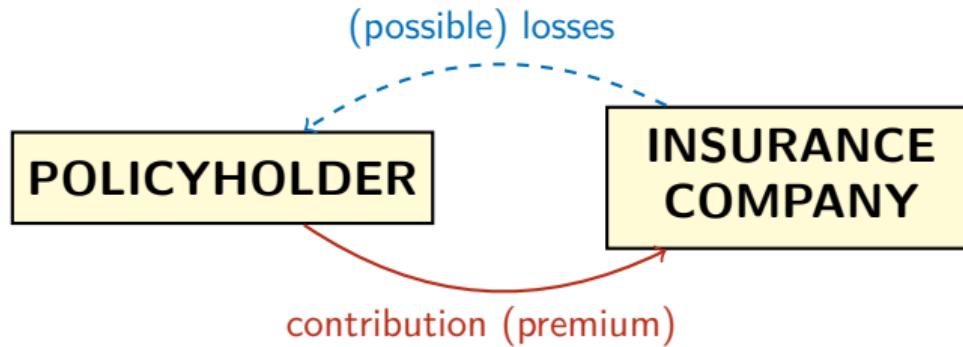

We have an **fairness of good calibration** if

$$\mathbb{P}[Y = 1 | \hat{Y} = y, P = 0] = \mathbb{P}[Y = 1 | \hat{Y} = y, P = 1] = y, \quad \forall y \in (0, 1).$$

See [Charpentier \(2022, 2023\)](#) for more details .

Insurance

“Insurance is the contribution of the many to the misfortune of the few ”

The “*contribution* ” is obtained using predictive models
(interpretability / black box / etc issues)

A model, $m : \mathbf{x} \mapsto y$

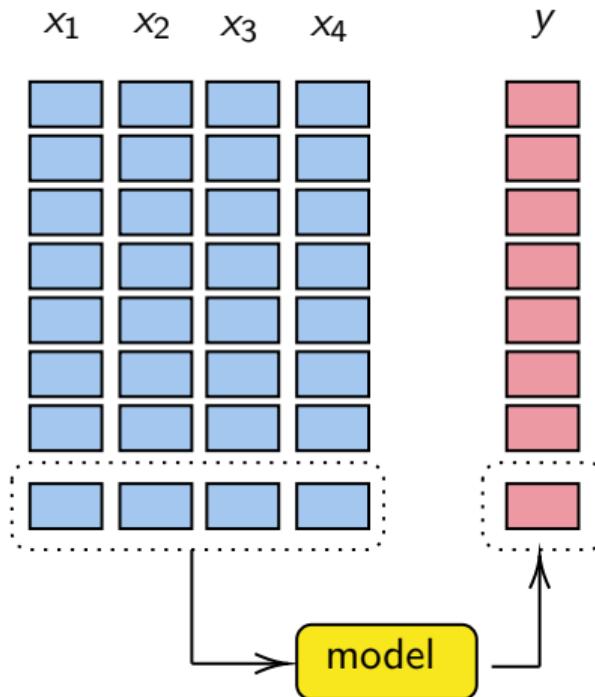

To train / estimate a model m ,
we need a dataset, i.e. a collection
of observations (\mathbf{x}_i, y_i)

Usually y_i denotes the annual loss

$$y_i = \sum_{j=1}^{n_i} z_{i,j}$$

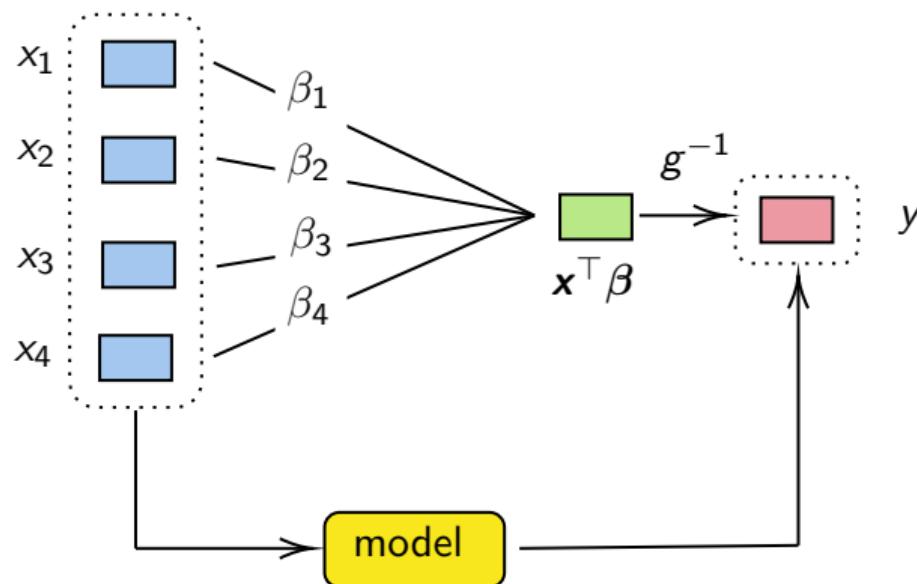

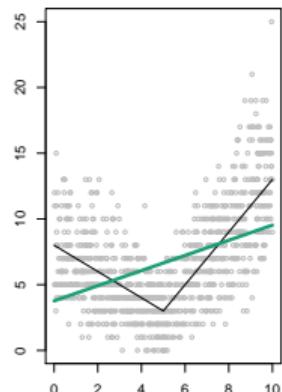

n is the annual frequency
 z is the cost of a single claim
(see Tweedie models)

To illustrate, y is a counting variable

A model, $m : \mathbf{x} \mapsto y$ (GLM)

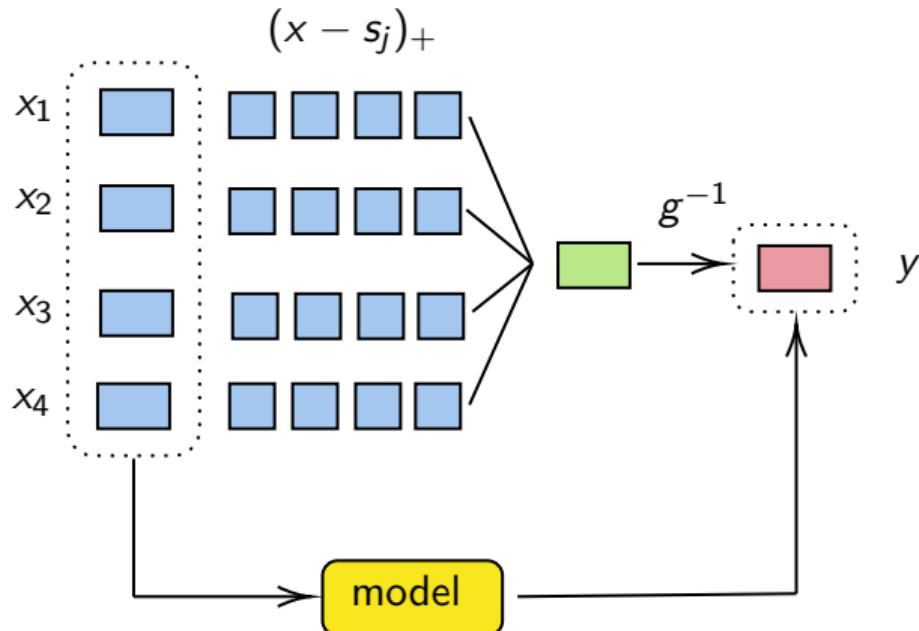

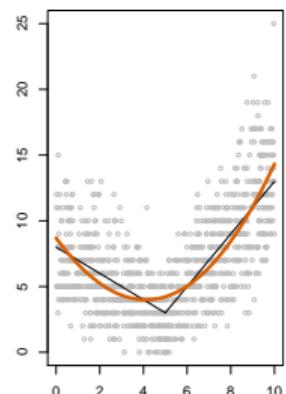

Poisson regression

$$m(\mathbf{x}) = g^{-1}(\mathbf{x}^\top \boldsymbol{\beta}) = g^{-1} \left(\sum_{j=1}^p \beta_j x_j \right)$$

A model, $m : \mathbf{x} \mapsto y$ (GAM)

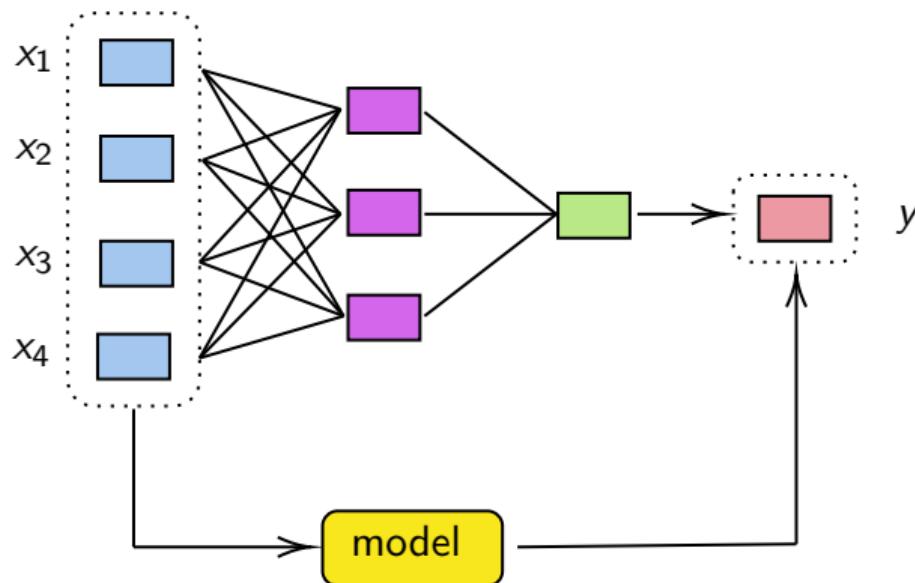

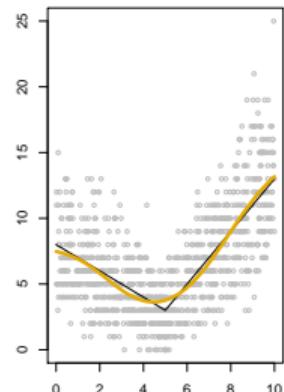

Poisson regression

$$m(\mathbf{x}) = g^{-1} \left(\sum_{j=1}^p \beta_j \psi_j(x_j) \right), \text{ where } \psi_j(x) = \sum_{k=1}^5 \alpha_{j,k} (x - s_{j,k})_+$$

A model, $m : \mathbf{x} \mapsto y$ (neural nets)

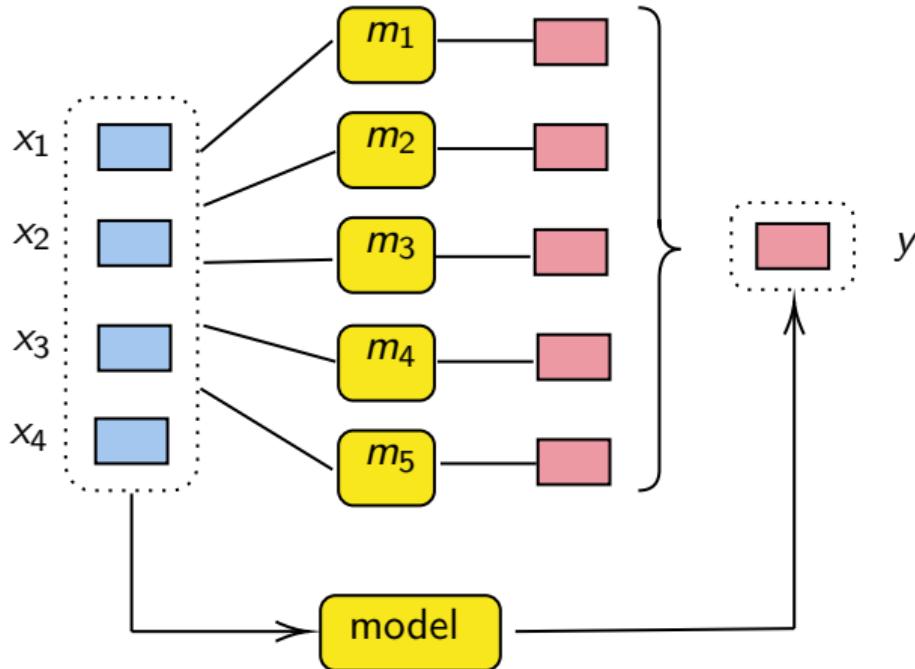

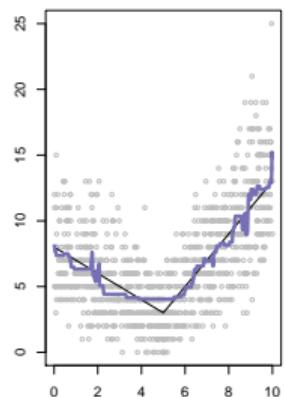

Poisson loss

$$\text{E.g. } m(\mathbf{x}) = \sum_{j=1}^3 \omega_{1:j} h(\mathbf{x}^\top \boldsymbol{\omega}_{2:j})$$

A model, $m : \mathbf{x} \mapsto y$ (ensemble parallel, bagging)

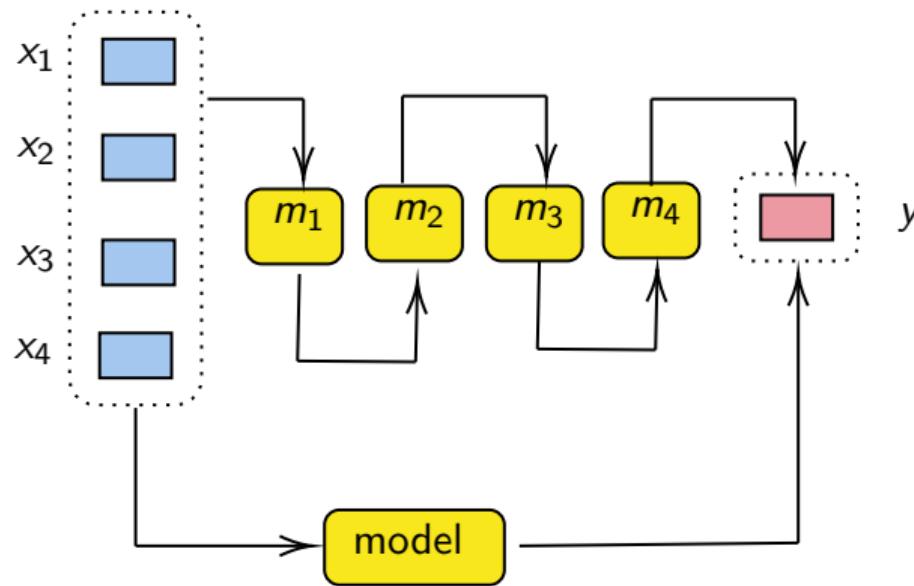

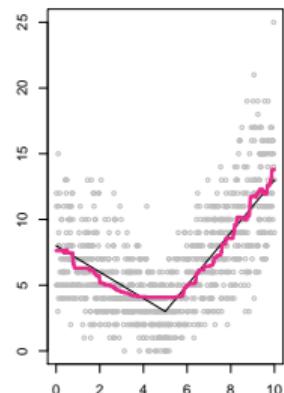

Random forest

E.g. $m(\mathbf{x}) = \frac{1}{B} \sum_{b=1}^B m_b(\mathbf{x})$ where $m_b(\mathbf{x}) = \sum_{k=1}^K \alpha_{b,k} \mathbf{1}(\mathbf{x} \in \mathcal{X}_{b,k})$

A model, $m : \mathbf{x} \mapsto y$ (ensemble sequential, boosting)

Boosting

$$m(\mathbf{x}) = \sum_{t=1}^T m_t(\mathbf{x})$$
 where m_t is a (weak) model on $y_i - m_{t-1}(\mathbf{x}_i)$
(residuals from the previous step) such as (not too deep) trees

Not a model, $\hat{m} : \mathbf{x} \mapsto y$ (local regression)

To approximate $\mathbb{E}[Y]$ use

$$\hat{m} = \underset{\mu \in \mathbb{R}}{\operatorname{argmin}} \left\{ \sum_{i=1}^n \frac{1}{n} [y_i - \mu]^2 \right\}$$

To approximate $\mathbb{E}[Y | \mathbf{X} = \mathbf{x}]$, use

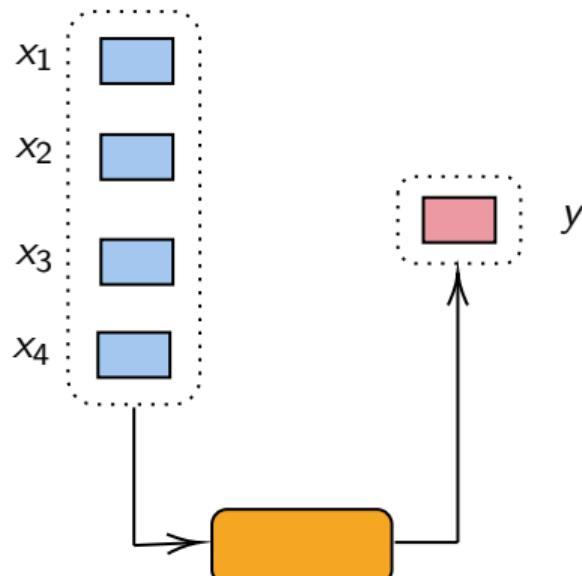

$$\hat{m}(\mathbf{x}) = \underset{\mu \in \mathbb{R}}{\operatorname{argmin}} \left\{ \sum_{i=1}^n \omega_i(\mathbf{x}) [y_i - \mu]^2 \right\}$$

where, see Loader (1999),

$$\omega_i(\mathbf{x}) \propto k_\alpha (\|\mathbf{x} - \mathbf{x}_i\|)$$

or k nearest neighbors indicator...

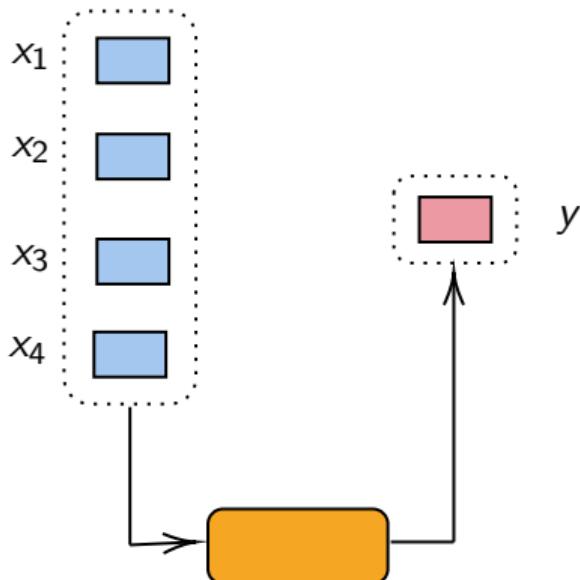

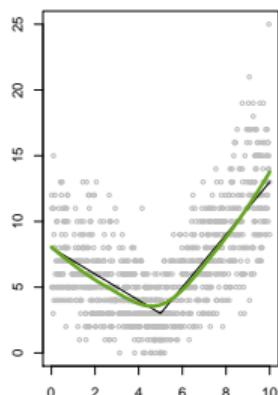

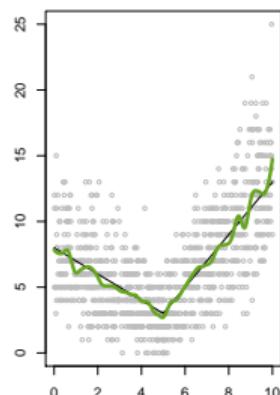

Behaves poorly in high dimension (but efficient in dimension 1)

Not a model, $\hat{m} : \mathbf{x} \mapsto y$ (local regression)

$$\hat{m}(\mathbf{x}) = \sum_{i=1}^n \omega_i(\mathbf{x}) y_i, \text{ with } \sum_{i=1}^n \omega_i(\mathbf{x}) = 1$$

see `locfit` in R

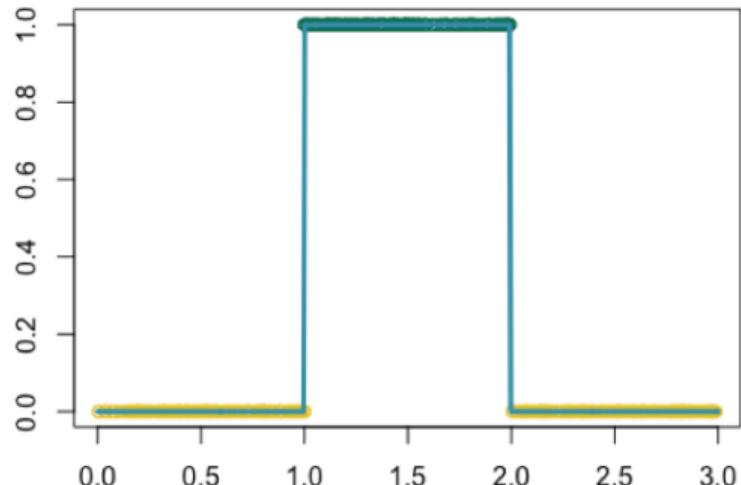

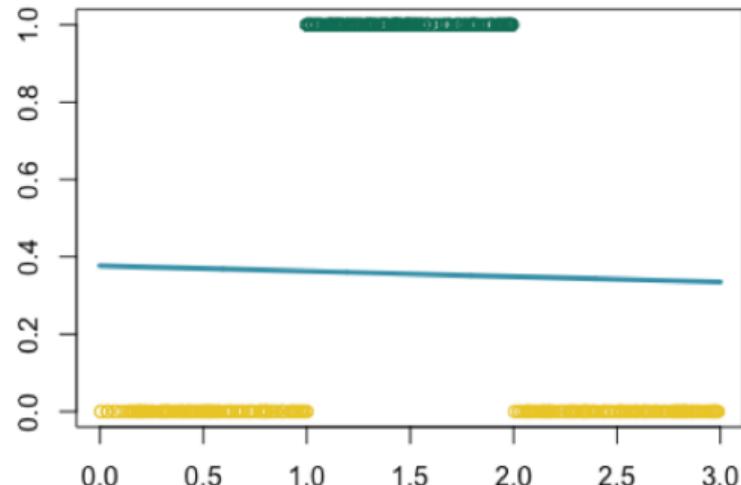

(depends on a bandwidth parameter α)

Provides a local estimate of $\mathbb{E}[Y|X = x]$ on a neighborhood of x

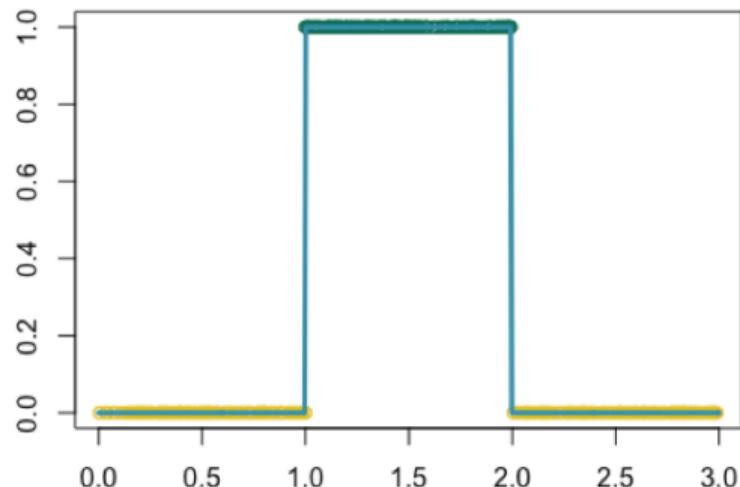

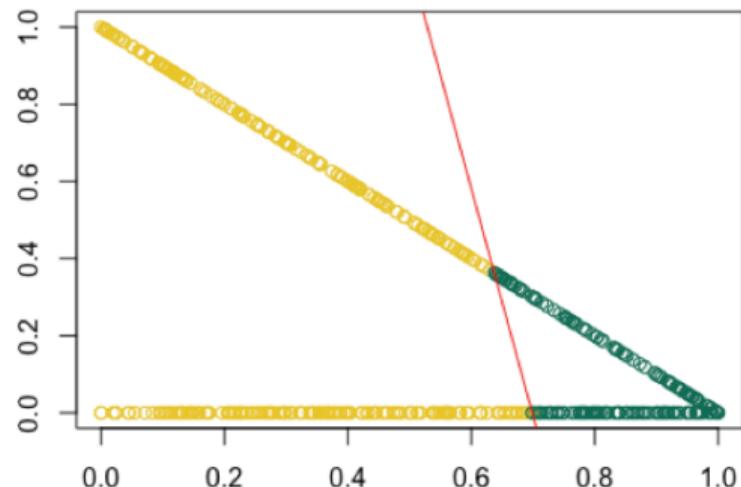

GLM, GAM & Neural Nets

Consider some simple dataset $\{(x_i, y_i)\}$.
Fit a GLM and a GAM (linear, 3 knots)

GLM, GAM & Neural Nets

Consider some simple dataset $\{(x_i, y_i)\}$.
Fit a GLM and a GAM (linear, 3 knots)

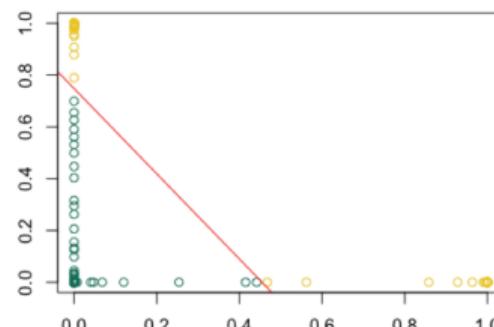

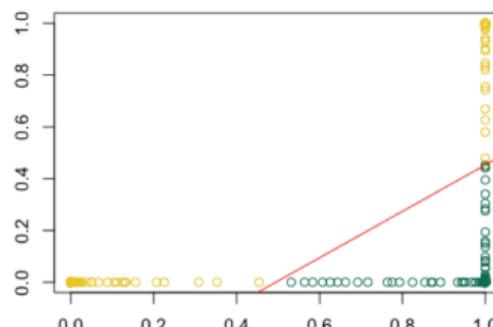

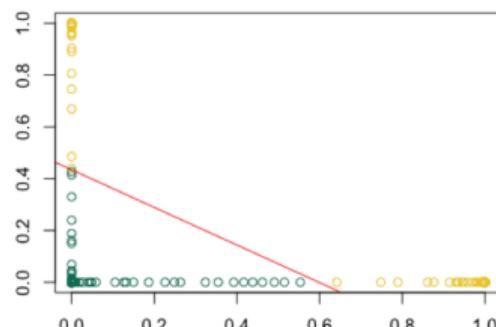

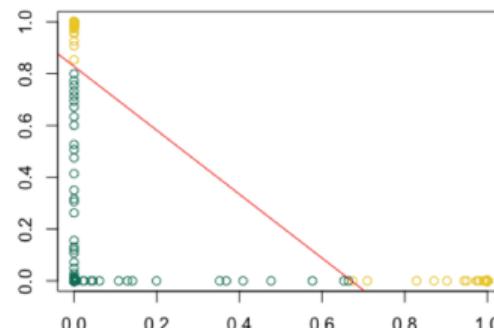

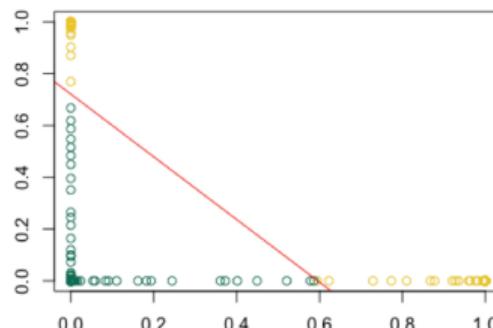

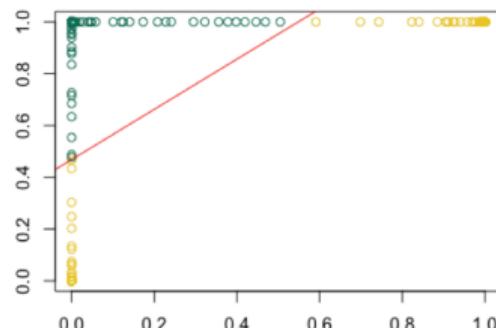

Two variables, $x_1 = (x - s_1)_+$ and $x_2 = (x - s_2)_+$

GLM, GAM & Neural Nets

Consider some simple dataset $\{(x_i, y_i)\}$.

Fit a Neural Net

GLM, Bias, & Economic Interpretation

For GLMs, $f(y_i) = \exp\left(\frac{y_i\theta_i - b(\theta_i)}{\varphi} + c(y_i, \varphi)\right)$

The natural parameter for y_i : θ_i

Prediction for y_i : $\hat{y}_i = \mu_i = \mathbb{E}(Y_i) = b'(\theta_i)$

Score associated with y_i : $\eta_i = \mathbf{x}_i^\top \beta$

Link function : g such that $\eta_i = g(\mu_i) = g(b'(\theta_i))$

$$\log \mathcal{L}(\boldsymbol{\theta}, \varphi, \mathbf{y}) = \sum_{i=1}^n \log \mathcal{L}_i = \sum_{i=1}^n \left[\frac{y_i\theta_i - b(\theta_i)}{\varphi} + c(y_i, \varphi) \right]$$

First order conditions: $\frac{\partial \log \mathcal{L}_i}{\partial \beta_j} = \frac{\partial \log \mathcal{L}_i}{\partial \theta_i} \cdot \frac{\partial \theta_i}{\partial \mu_i} \cdot \frac{\partial \mu_i}{\partial \eta_i} \cdot \frac{\partial \eta_i}{\partial \beta_j}$

$$\frac{\partial \log \mathcal{L}_i}{\partial \theta_i} = \frac{y_i - \mu_i}{\varphi}, \quad \frac{\partial \theta_i}{\partial \mu_i} = \left(\frac{\partial \mu_i}{\partial \theta_i} \right)^{-1} = \frac{1}{b''(\theta_i)} = \frac{1}{V(\mu_i)}$$

$$\frac{\partial \eta_i}{\partial \beta_j} = \frac{\partial \mathbf{x}_i^\top \beta}{\partial \beta_j} = x_{i,j}, \quad \frac{\partial \mu_i}{\partial \eta_i} = \left(\frac{\partial \eta_i}{\partial \mu_i} \right)^{-1} = (g'(\mu_i))^{-1}$$

GLM, Bias, & Economic Interpretation

With canonical link $g_\star = b'^{-1}$, i.e. $\eta_i = \theta_i$,

$$\mathbf{X}^\top(\mathbf{y} - \boldsymbol{\mu}) = \mathbf{0}, \text{ where } \hat{\mathbf{y}} = \boldsymbol{\mu}$$

so, if there is an intercept, $\mathbf{1}^\top(\mathbf{y} - \boldsymbol{\mu}) = \mathbf{0}$, i.e. $\sum_{i=1}^n y_i = \sum_{i=1}^n \hat{y}_i$

which is the empirical version (training dataset) of $\mathbb{E}[Y] = \mathbb{E}[\hat{Y}]$
(see logistic regression or Poisson with log-link)

But more generally, the first order condition is

$$\mathbf{X}^\top \mathbf{W} \Delta (\mathbf{y} - \boldsymbol{\mu}) = \mathbf{0},$$

where $\mathbf{W} = \text{diag}((V(\mu_i)g'(\mu_i)^2)^{-1})$ and $\Delta = \text{diag}(g'(\mu_i))$.

But usually not an important issue in ML classification problems

GLM, Bias, & Economic Interpretation

Model $\hat{\pi}$ is **globally unbiased** if $\mathbb{E}[\hat{\pi}(\mathbf{X})] = \mathbb{E}[Y]$, $\sum_{i=1}^n \hat{y}_i = \sum_{i=1}^n y_i$

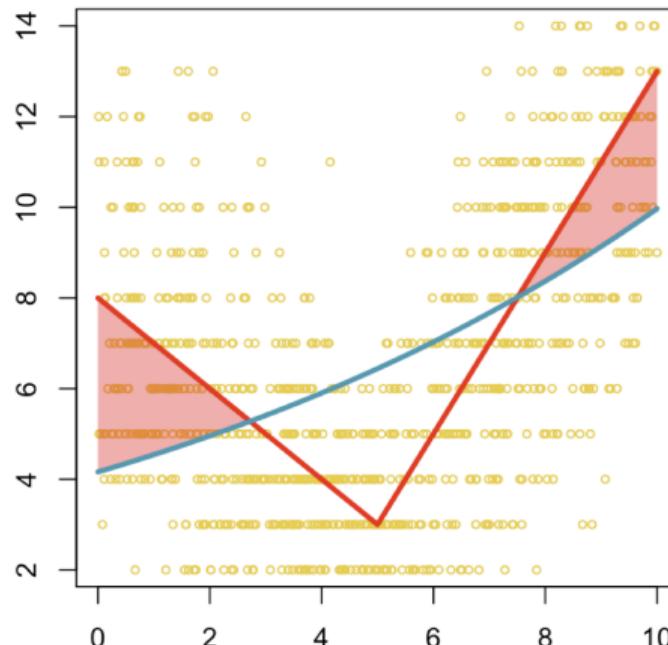

Model $\hat{\pi}$ is **locally unbiased** if $\mathbb{E}[Y|\hat{\pi}(\mathbf{X}) = s] = s$

GLM $\hat{\pi}$ globally unbiased,
but possibly **locally biased**

Major economic impact

- ▶ $\hat{\pi}(\mathbf{x}) < \mu(\mathbf{x})$
attractive, but underpriced
- ▶ $\hat{\pi}(\mathbf{x}) > \mu(\mathbf{x})$
not attractive

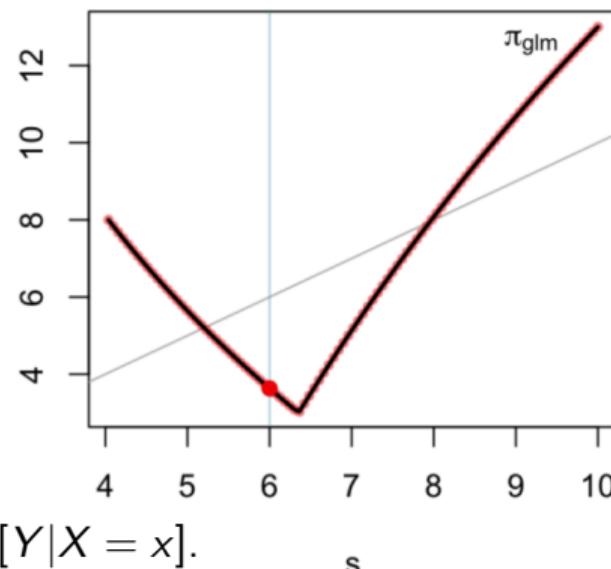

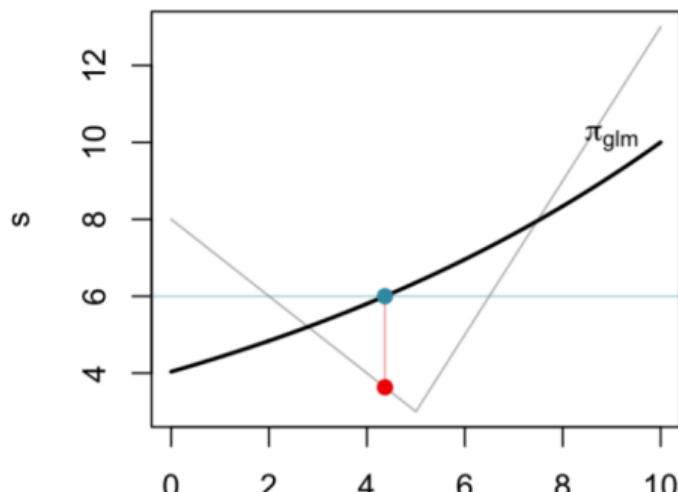

Natural idea: plot
 $s \mapsto \mathbb{E}[Y|\hat{\pi}(\mathbf{X}) = s] = \mu(\hat{\pi}^{-1}(s))$

Computing $\mathbb{E}[Y|\hat{\pi}(\mathbf{X}) = s]$

True model $\mu(x)$ and GLM model $\hat{\pi}(x)$

- ▶ select s , e.g. $s = 6$
- ▶ compute $x = \hat{\pi}^{-1}(s)$ ($\hat{\pi}$ is strictly increasing), here $x = 4.2$
- ▶ compute $\mu(\hat{\pi}^{-1}(s))$, here 3.8
- ▶ plot $(s, \mu(\hat{\pi}^{-1}(s)))$

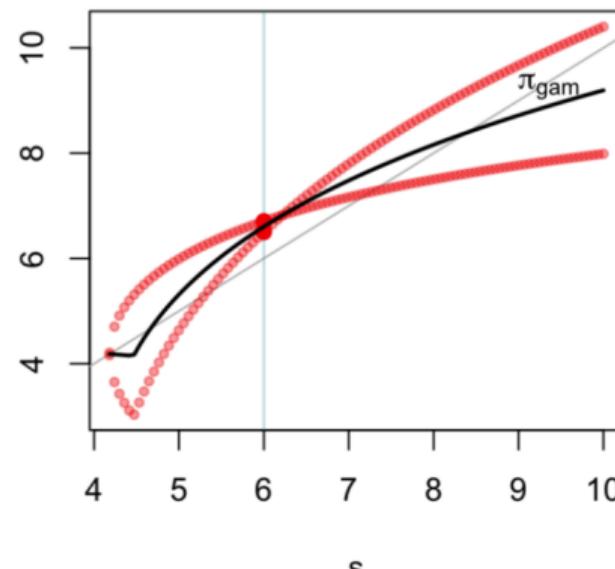

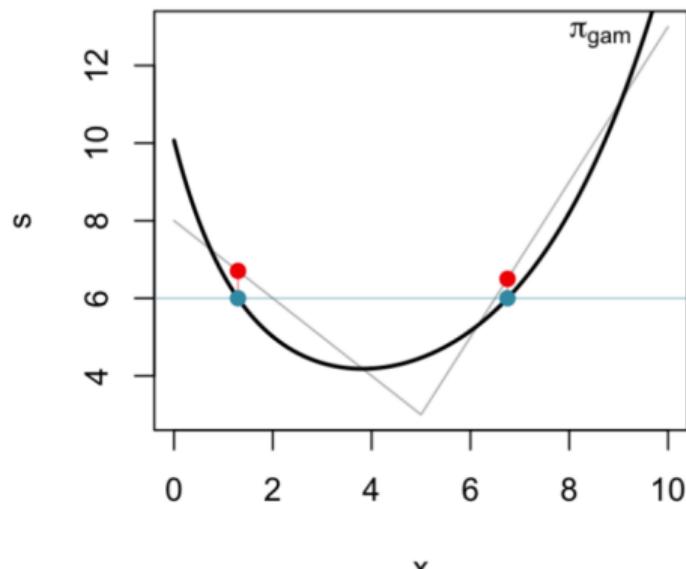

$$s \mapsto \mathbb{E}[Y|\hat{\pi}(\mathbf{X}) = s] = \mu(\hat{\pi}^{-1}(s)) \text{ since } \mu(x) = \mathbb{E}[Y|X = x].$$

Computing $\mathbb{E}[Y|\hat{\pi}(\mathbf{X}) = s]$

True model $\mu(x)$ and GAM model $\hat{\pi}(x)$

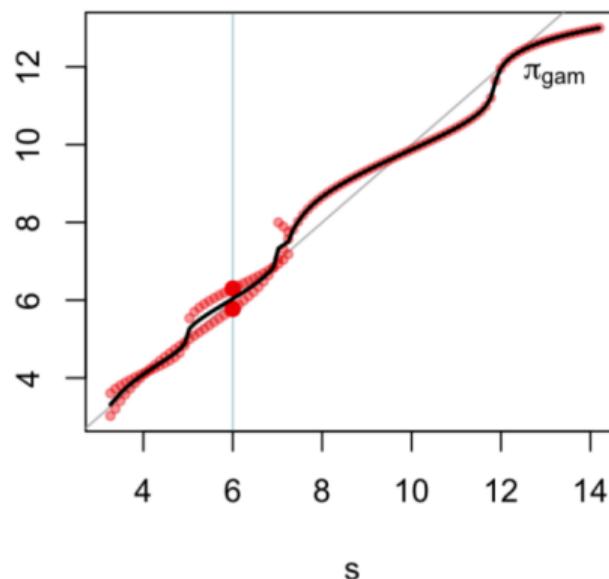

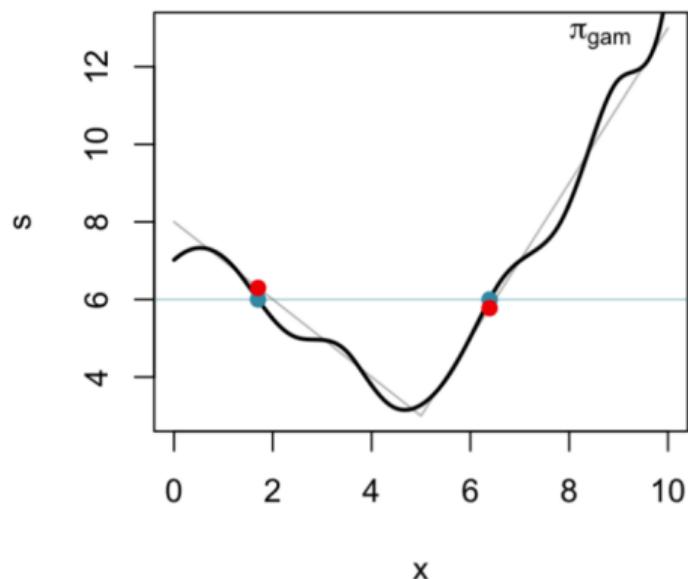

- ▶ select s , e.g. $s = 6$
- ▶ compute $\mathcal{X}_s^{\hat{\pi}} = \{\mathbf{x} \in \mathcal{X}, \hat{\pi}(\mathbf{x}) = s\}$, here $\{1.6; 6.7\}$
- ▶ compute $\mu(\hat{\pi}^{-1}(s))$, $\{6.4, 6.2\}$ and its mean $\bar{\mu}(\hat{\pi}^{-1}(s))$, 6.3
- ▶ plot $(s, \bar{\mu}(\hat{\pi}^{-1}(s)))$

Computing $\mathbb{E}[Y|\hat{\pi}(\mathbf{X}) = s]$

True model $\mu(x)$ and GAM model $\hat{\pi}(x)$ (more degrees of freedom)

Plot $s \mapsto \mathbb{E}[Y|\hat{\pi}(X) = s]$, should be close to the first diagonal

Seems locally unbiased...

- ▶ impossible to get the figure on the left in higher dimension
- ▶ we used here μ but in practice, μ is unknown !

$\mathbb{E}[Y|\hat{\pi}(\mathbf{X}) = s]$: empirical version

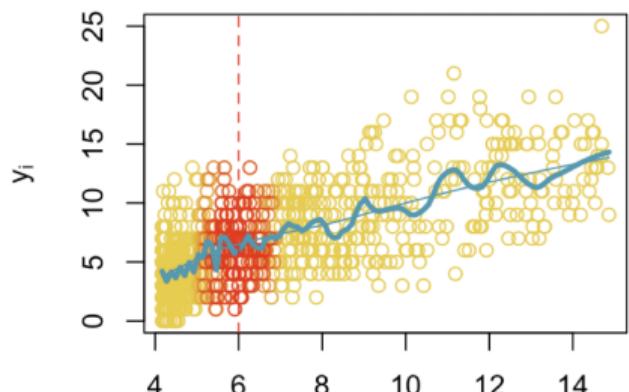

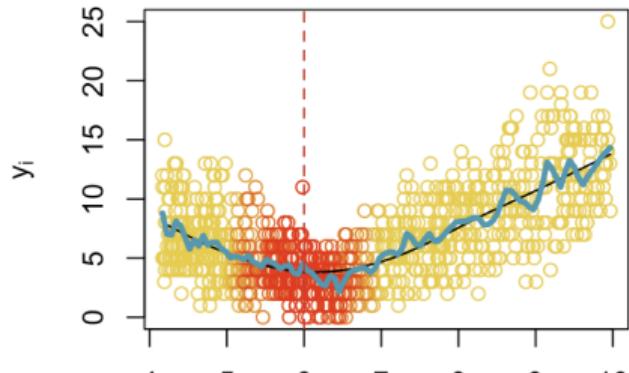

How to plot $s \mapsto \mathbb{E}[Y|\hat{\pi}(X) = s]$?

but in real life, μ is unknown

Consider $\{(\hat{\pi}(\mathbf{x}_i), y_i)\}$

and fit a local regression

- ▶ fit a model $\hat{\pi}$
 - ▶ estimate $\mathbb{E}[Y|\hat{\pi}(X) = s]$
local regression on $\{(\hat{\pi}(\mathbf{x}_i), y_i)\}$
 - ▶ local (multiplicative) correction
- $$\lambda_\alpha(s) = \frac{\mathbb{E}[Y|\hat{\pi}(X) = s]}{s}$$
- ▶ correct $\hat{\pi}$
- $$\hat{\pi}_{BC}(\mathbf{x}) = \lambda_\alpha(\hat{\pi}(\mathbf{x})) \cdot \hat{\pi}(\mathbf{x})$$

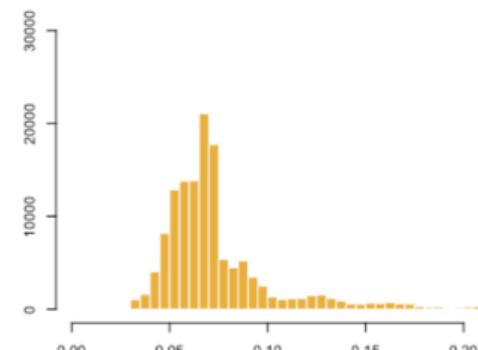

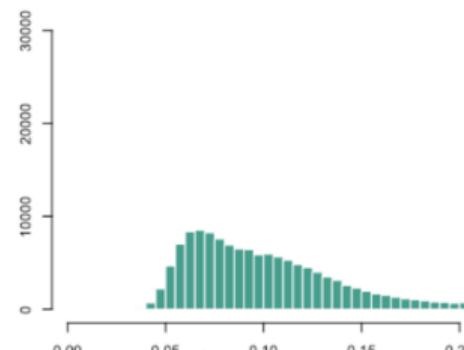

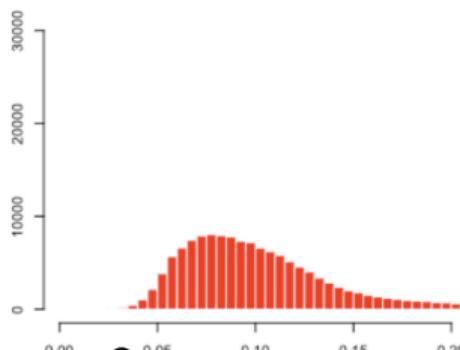

Application of a motor-insurance dataset

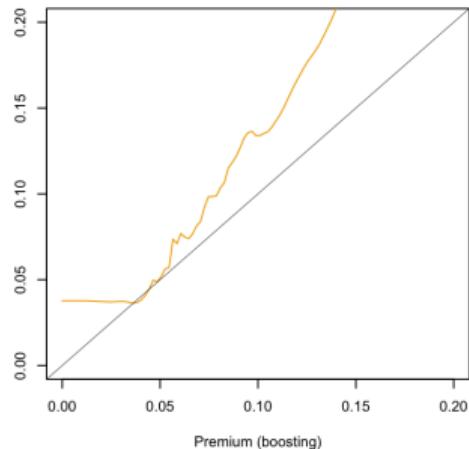

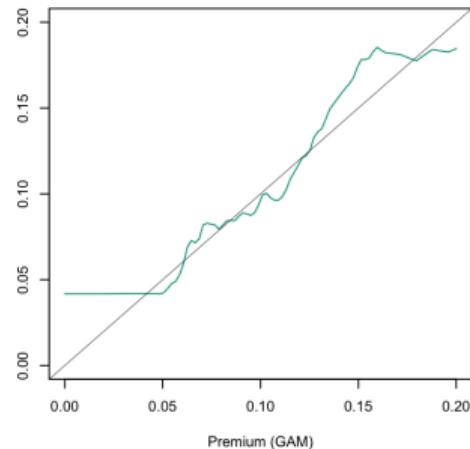

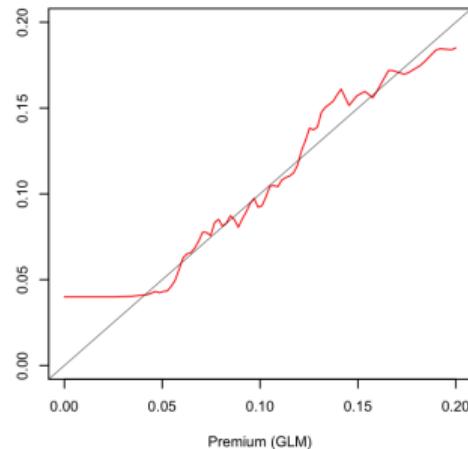

Here we focus only on claims (annual) frequency, corrected from the exposure,
`freMTPL2freq` from `CASDataset` package, 

	π^{glm}	π^{gam}	π^{bst}
average $\bar{\pi}$	0.1087	0.1092	0.0820
10% quantile	0.0605	0.0598	0.0498
90% quantile	0.1682	0.1713	0.1244

Table 1: Summary statistics on $\{\pi(\mathbf{x}_1), \dots, \pi(\mathbf{x}_n)\}$, on the validation dataset (assuming an exposure of 1 to provide annualized predictions).

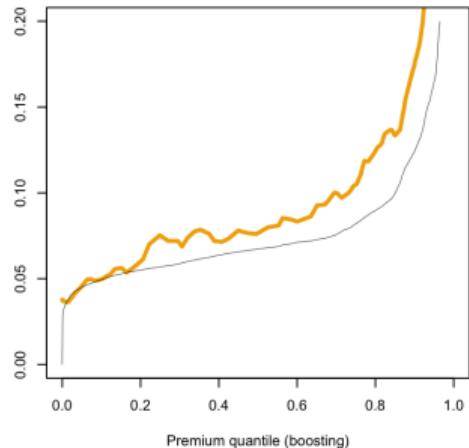

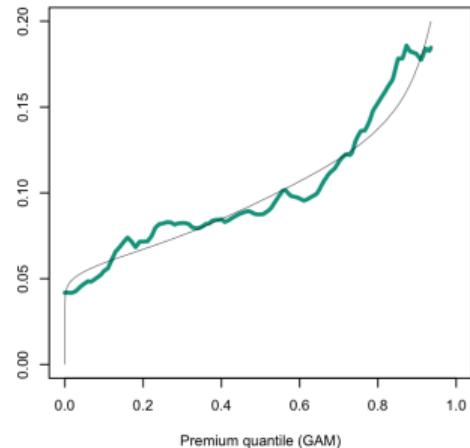

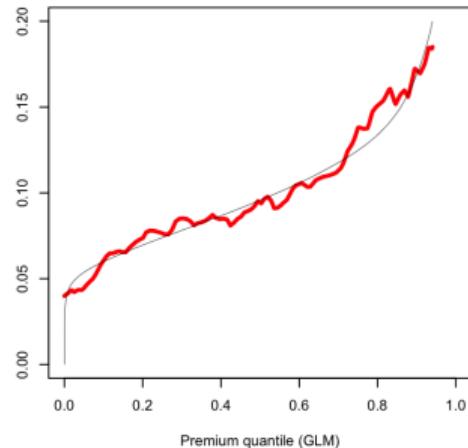

Application of a motor-insurance dataset

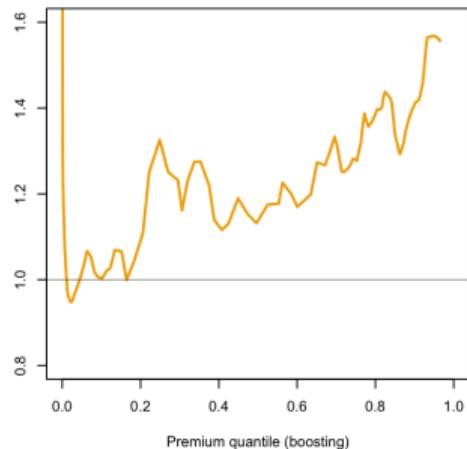

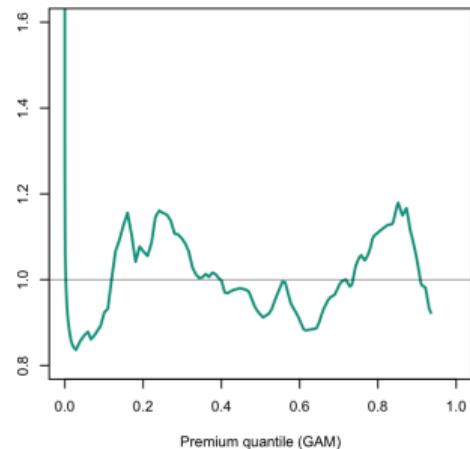

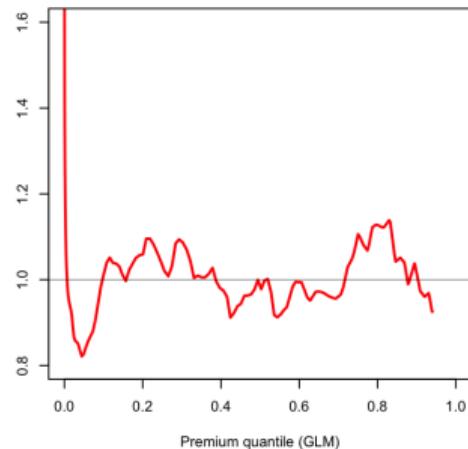

Evolution of $s \mapsto \mathbb{E}[Y|\hat{\pi}(\mathbf{X}) = s]$

Application of a motor-insurance dataset

Evolution of $u \mapsto \mathbb{E}[Y|\hat{\pi}(\mathbf{X}) = F_\pi^{-1}(u)]$

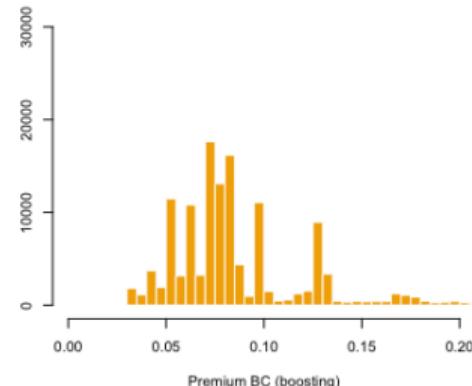

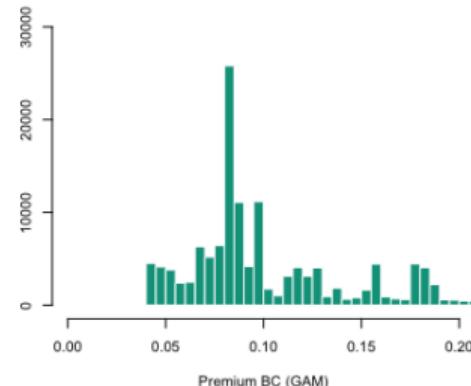

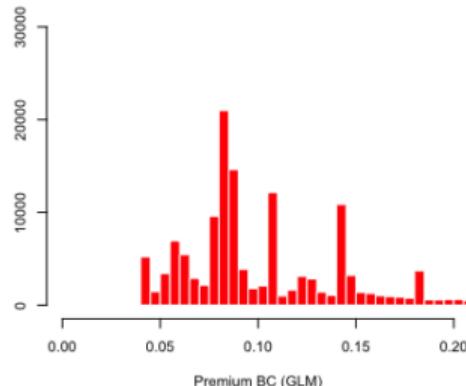

Application of a motor-insurance dataset

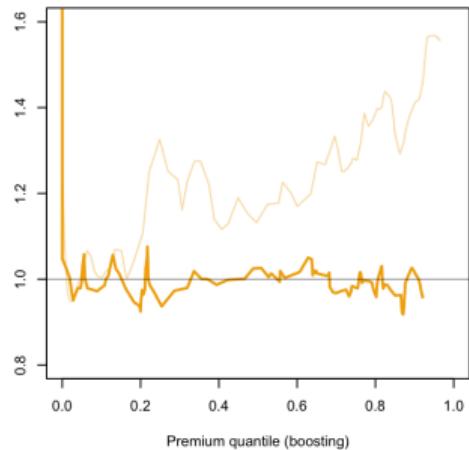

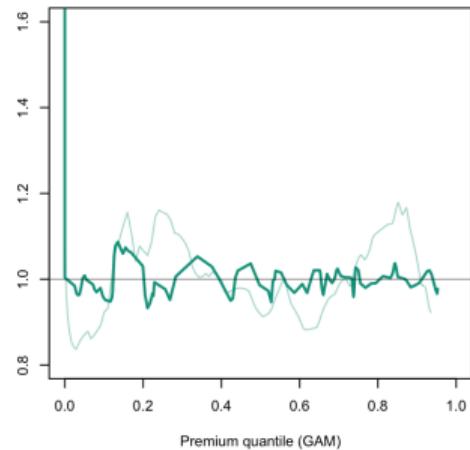

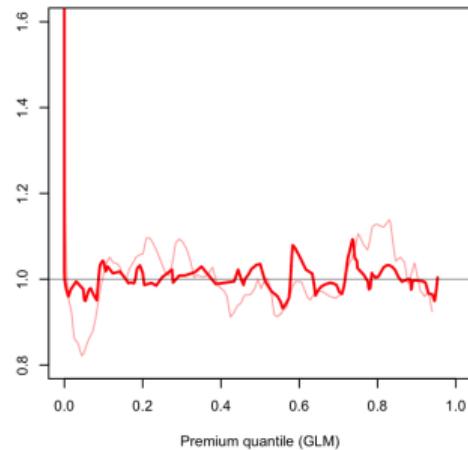

Multiplicative correction $\lambda_\alpha(u) = \mathbb{E}[Y|\hat{\pi}(\mathbf{X}) = F_{\hat{\pi}}^{-1}(u)]/F_{\hat{\pi}}^{-1}(u)$

Application of a motor-insurance dataset

Multiplicative correction $\lambda_\alpha(u) = \mathbb{E}[Y|\hat{\pi}(\mathbf{X}) = F_{\hat{\pi}}^{-1}(u)]/F_{\hat{\pi}}^{-1}(u)$

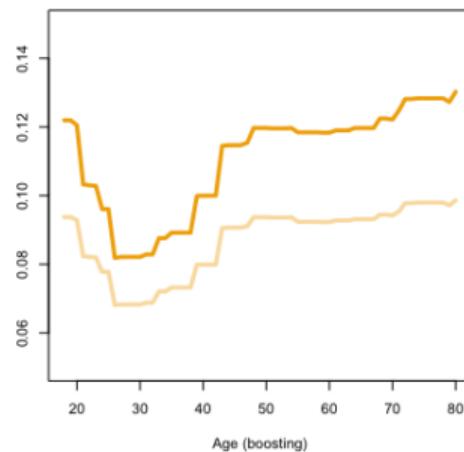

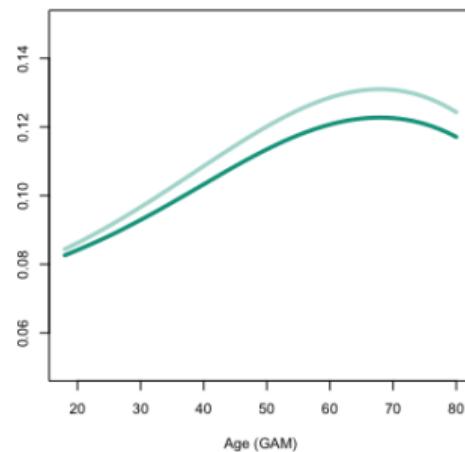

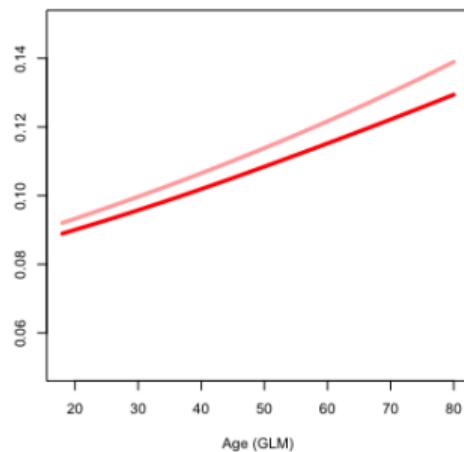

Application of a motor-insurance dataset

λ_α on the corrected model $\hat{\pi}_{BC}$,

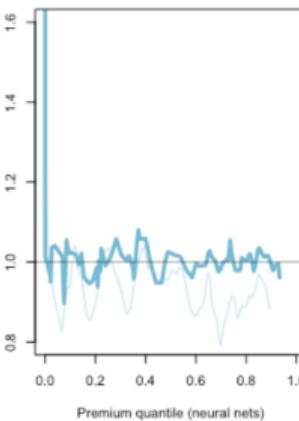

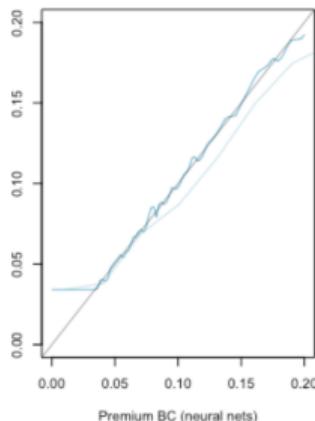

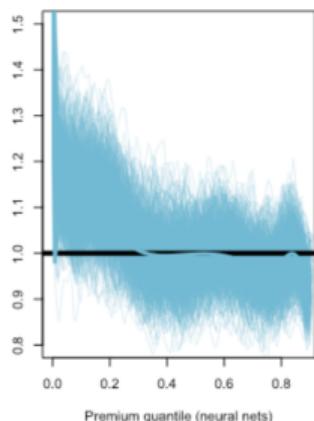

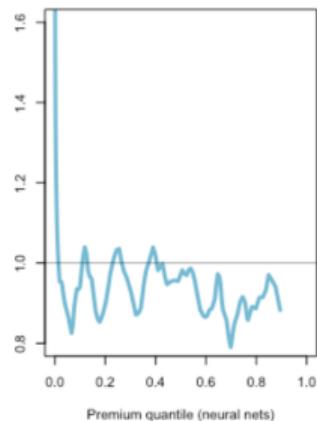

Application of a motor-insurance dataset

some partial dependence plot
(on the age of the driver)

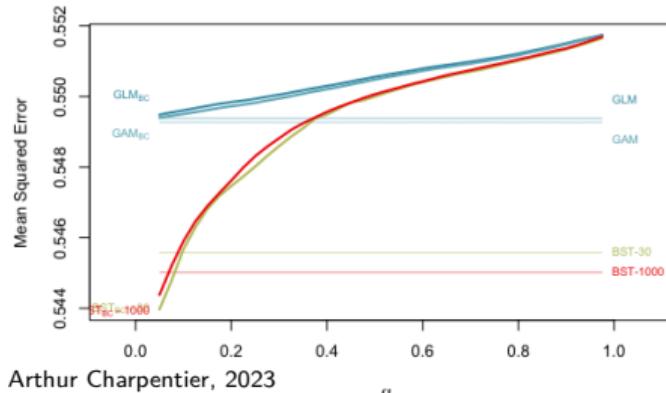

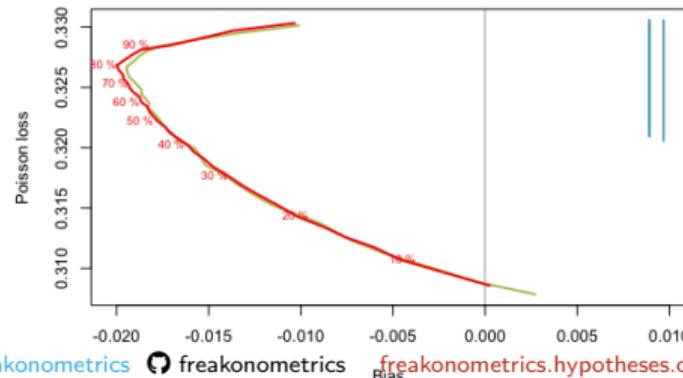

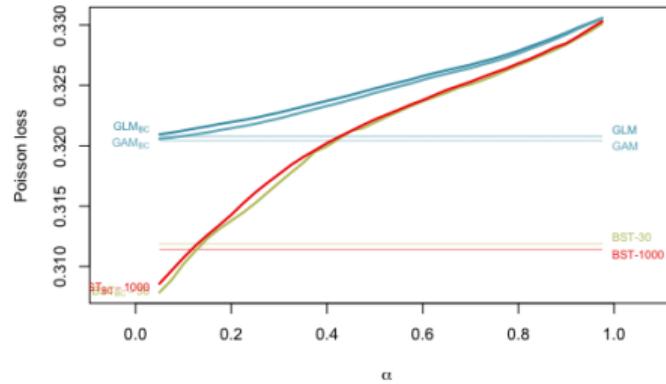

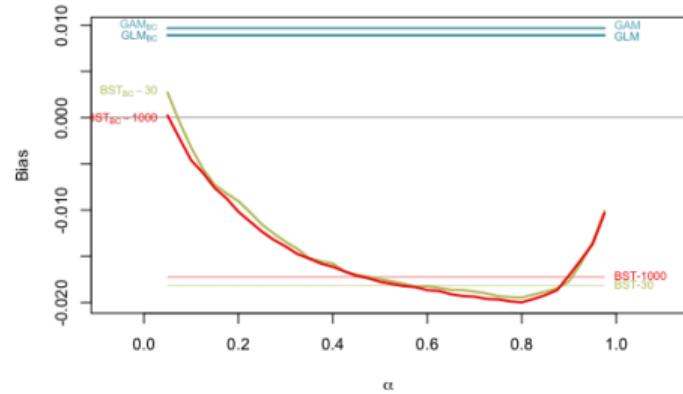

Using Neural Nets on motor-insurance dataset

We can also look at neural networks performance

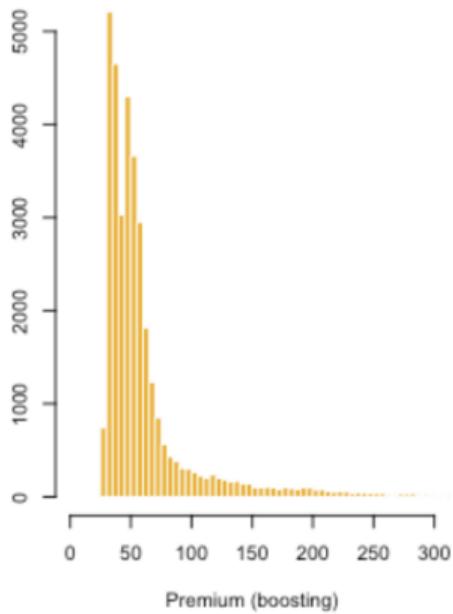

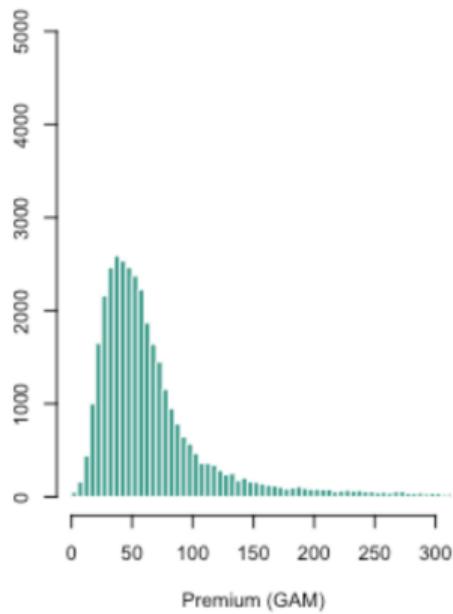

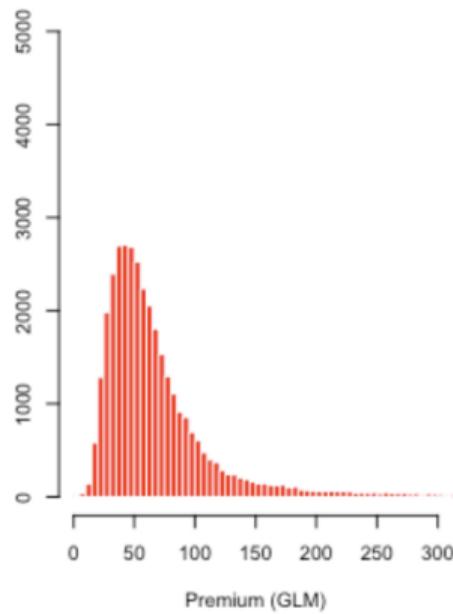

Reproducibility issues here

Choice of α

Tweedie model on motor-insurance dataset

Wrap-Up

- ▶ fit a model $\hat{\pi}$ using an ML algorithm
- ▶ estimate $\mathbb{E}[Y|\hat{\pi}(X)]$ with local regression on $\{(\hat{\pi}(\mathbf{x}_i), y_i)\}$
- ▶ local (multiplicative) correction $\lambda_\alpha(s) = \frac{\mathbb{E}[Y|\hat{\pi}(X) = s]}{s}$
- ▶ correct $\hat{\pi}$ by setting $\hat{\pi}_{BC}(\mathbf{x}) = \lambda_\alpha(\hat{\pi}(\mathbf{x})) \cdot \hat{\pi}(\mathbf{x})$
